## **Documentation Updates**

The title page of this document contains the following identifying information:

- Software Version number, which indicates the software version.
- Document Release Date, which changes each time the document is updated.
- Software Release Date, which indicates the release date of this version of the software.

To check for recent updates or to verify that you are using the most recent edition of a document, go to:

#### http://h20230.www2.hp.com/selfsolve/manuals

This site requires that you register for an HP Passport and sign in. To register for an HP Passport ID, go to:

#### http://h20229.www2.hp.com/passport-registration.html

Or click the New users - please register link on the HP Passport login page.

You will also receive updated or new editions if you subscribe to the appropriate product support service. Contact your HP sales representative for details.

#### **Document Changes**

Chapter	Date	Version	Changes
	June 2010	9.0	Document Created
	June 2010	9.0	OCLI content moved to SA User Guide: Server Automation
IDK Overview	May 2011	9.10	Added "Intalling the IDK on an Unmanaged Server'

## Support

Visit the HP Software Support Online web site at:

#### www.hp.com/go/hpsoftwaresupport

This web site provides contact information and details about the products, services, and support that HP Software offers.

HP Software online support provides customer self-solve capabilities. It provides a fast and efficient way to access interactive technical support tools needed to manage your business. As a valued support customer, you can benefit by using the support web site to:

- Search for knowledge documents of interest
- Submit and track support cases and enhancement requests
- Download software patches
- Manage support contracts
- Look up HP support contacts
- Review information about available services
- Enter into discussions with other software customers
- Research and register for software training

Most of the support areas require that you register as an HP Passport user and sign in. Many also require a support contract. To register for an HP Passport ID, go to:

#### http://h20229.www2.hp.com/passport-registration.html

To find more information about access levels, go to:

http://h20230.www2.hp.com/new\_access\_levels.jsp

#### **About This Guide**

Welcome to HP Server Automation (SA) — an enterprise-class software solution that enables customers to get all the benefits of data center automation platform and support services. SA provides a core foundation for automating formerly manual tasks associated with the deployment, support, and growth of server and server application infrastructure.

This guide describes how to use the following command-line utilities:

- DCML Exchange Tool (DET) formerly the cbt command
- Intelligent Software Module Development Kit (IDK) ismtool and ismusertool

# 1 Import/Export SA Content

This guide is intended for system administrators responsible for specifying SA content (such as installable packages). To understand the material in this guide, you should be familiar with script programming, package installation, and SA fundamentals.

## The DCML Exchange Utility (DET)

The DCML Exchange Utility (DET) exports and imports SA content. DET enables you to inject a newly-installed SA Multimaster Mesh with content from an existing mesh. This tool can also be used to export partial content from one mesh and import it into other mesh instances.

In the context of DET, *content* means user-created SA server management information. This includes the following content types:

- Applications, Application Configurations
- Application Configuration Templates
- Custom Extensions
- Custom Fields Schema, Customers
- Distributed Scripts
- Folders
- SOs
- Packages
- Patches
- Patch Policies
- Server Compliance Criteria
- Device Groups
- User Groups.

Associated content information includes

- MRLs
- Install Hooks
- Configuration Tracking Policies
- Custom Attributes
- Custom Field Schemas
- Custom Fields.

Content does not include managed environment type information. For example, facility information and server properties are not included. Also, CD&R is not included in this release of DET.

DET is a command-line utility that you can run on any Unix host with network connectivity to a target SA mesh. DET is written in Java and uses OWL and RDF for its schema definition and persistent store. DET imports and exports SA content by using SA component APIs to extract both configuration and large binary content, such as packages and scripts.

## DET Relationship to DCML

The content exported by the DET is in compliance with DCML Framework Specification v0.11, the first publicly-available specification of DCML. The DCML Exchange Tool uses a proprietary extension schema to describe contents exported from HP Server Automation. The exported data.rdf is a valid DCML instance document that is parsable by a compliant DCML processor.

## Custom Fields and Custom Attributes

Each custom field exists in a namespace. The DET only has access to (and thus will only export) these objects in the default, user-visible namespace. Objects in other namespaces (OPSWARE, etc.) will not be exported. If objects in other namespaces need to be exported (for example, OS sequences), they will be exported via application-specific APIs (for example, OS sequence APIs).

All custom attributes are exported, including those that are hidden from end-users (those keys starting with OPSW).

For custom fields and attributes, imported values (including nulls) overlay existing values.

## Installing and Configuring DET

The following instructions detail how to install and configure the DCML Exchange Tool (DET).

The DCML Exchange Tool (DET) can be run on any UNIX computer, though not necessarily a managed server. (Although DET is not supported on the Windows platform, it does support import and export of Windows content.)

- 1 Log on as root to a server managed by HP Server Automation.
- 2 Obtain the HP Server Automation installation media.
- 3 Mount the HP Server Automation product DVD.
- 4 On the DVD, locate the cbt-<version>.zip file, which resides in the packages subdirectory.
- 5 Copy the zip file to the directory where you want to install DET.

- 6 Unzip the zip file.
- 7 If you do not already have them, download JRE 1.4.x or JDK 1.6.x from www.sun.com, and install it on the server where you have logged in.
- Set your JAVA\_HOME environment variable to point to a Java 1.4.x installation. For example, in csh you would issue the following command:

```
% setenv JAVA HOME < j2re 1.4.x installation>
```

- 9 Optionally, you can set the PATH environment variable to include the DET install directory: <cbt-install dir>/bin.
- 10 To verify that you have performed the previous steps correctly, enter the following commands:

```
% cd <cbt-install_dir>/bin
% ./cbt -v
```

The cbt executable script launches the DET utility. The -v option should display the command's version string.

On some servers, the cbt command displays the following error:

```
Error occurred during initialization of VM Could not reserve enough space for object heap
```

If this error occurs, then edit the cbt script, changing the value of the -Xmx option in jargs to a lower value, for example: -Xmx512m.

- 11 Perform the following steps for each mesh that DET will be importing into or exporting from.
  - Obtain a copy of the opsware-ca.crt trust certificate from /var/opt/opsware/crypto/twist/opsware-ca.crt and save it in a location DET can access. This step is optional if you are running DET from the server where the Command Center core component is installed.
  - b Obtain a copy of the spog.pkcs8 client certificate from /var/opt/opsware/crypto/twist/spog.pkcs8 and save it in a location DET can access. This step is optional if you are running DET from the server where the Command Center core component is installed.
  - c Obtain the twist user name and password this is set during the twist install and the SA administrator should have this information.
  - d Create a target mesh configuration file that contains the location and identity information required to access the SA mesh components. For details on this task, see the following section.

## Creating a Target Mesh Configuration File

Create a target mesh configuration file to simplify the use of DET. A sample default configuration file is installed with DET at the following location:

```
cbt/cfg/default.properties
```

The mesh configuration file is a key=value pair text file that contains SA component access information that would otherwise need to be given on the DET command-line. To define the parameters of the DET mesh configuration file, make a copy of this file and save it to a known location.

Import/Export SA Content 13

Because the configuration file contains user names and passwords, make sure it is secure.

Table 1 contains all possible DET configuration-related properties. These properties can be either given on the DET command-line or specified in a configuration file.

The default configuration property values listed in Table 1 assume that you are running DET on an SA mesh running the Command Center core component. (It is for this reason that the.host properties shows a localhost value.) Also, twist.certpaths, ssl.trustcerts, and ssl.keypairs assume paths on an Command Center server.

If a configuration-related property is not specifically mentioned in the mesh Configuration file, the default value shown in the Configuration Properties table below will be used.

**Table 1** Configuration Properties

Property Name	Default Value	Description
cbt.numthreads	1	Number of concurrent threads used for export.
		For exporting content, you can specify as many threads as you wish.
		However, for importing content, DET supports only one thread.
spike.enabled	true	Use Spike for authentication and authorization on all XML-RPC-based servers.
spike.host	way	Spike's host name or IP.
spike.path	wayrpc.py	Spike's base URL path.
spike.password	<no default=""></no>	User password for Spike authentication. This is an OCC user's password and is set during the installation of the mesh. Contact your SA Administrator (or the person who installed the mesh) for this information.
spike.port	1018	Spike's listener port.
spike.protocol	https	Spike's listener protocol. This is typically HTTPS.

 Table 1
 Configuration Properties (cont'd)

<b>Property Name</b>	Default Value	Description
spike.username	admin	User name for Spike authentication. This is the user who was granted permissions by the cbt-perm tool.
		This user name needs to be needs to be an admin account that has permissions to create or modify objects; however, it cannot be the detuser account. The det default configuration sets spike.username to account: admin
spin.host	spin	Data Access Engine's host name or IP.
spin.path	spinrpc.py	Data Access Engine's base URL path.
spin.port	1004	Data Access Engine's listener port.
spin.protocol	http	Data Access Engine's listener protocol. HTTP if the DET is on the same server as the SA Command Center and is running a clear text spin in a multi-server mesh or HTTPS for any other configuration
ssl.keyPairs	/var/opt/opsware/ crypto/twist/ spog.pkcs8	Comma-separated list of client certificates used to communicate with XML-RPC-based servers.
ssl.trustCerts	/var/opt/opsware/ crypto/twist/ opsware-ca.crt	Comma-separated list of trust certificate files used to communicate with XML-RPC-based servers.
ssl.useHttpClient	true	Use the HTTPClient library instead of JDK's built-in HTTP client.
twist.certPaths	/var/opt/opsware/ crypto/twist/ opsware-ca.crt	Comma-separated list of trust certificates used to communicate with the Web Services Data Access Engine.
twist.host	localhost	Web Services Data Access Engine's host name or IP.
twist.password	<no default=""></no>	Web Services Data Access Engine's password. This password is set during the installation of the mesh. Contact your SA Administrator (or the person who installed the mesh) for this information.

Import/Export SA Content 15

 Table 1
 Configuration Properties (cont'd)

Property Name	Default Value	Description
twist.port	1032	Web Services Data Access Engine's listening port.
twist.protocol	t3s	Web Services Data Access Engine's protocol. This should be t3 or t3s.
twist.username	detuser	Web Services Data Access Engine's user name. This needs to be "detuser". This account is a system account, and the password is set during install of the mesh.
way.host	way	Command Engine's host name or IP.
way.path	wayrpc.py	Command Engine's base URL path.
way.port	1018	Command Engine's listener port.
way.protocol	https	Command Engine's listener protocol. This is typically HTTPS.
word.host	word	Software Repository's host name or IP. As of SA 7.80, the Software Repository is part of the Slice Component bundle.
word.path	wordbot-new.py	Software Repository's base URL path.
word.port	1003	Software Repository's listener port.
word.protocol	https	Software Repository's listener protocol. This is HTTPS.
mail.transport.protocol	smtp	Mail transport protocol used for your mail server.
mail.smtp.host	smtp	Mail server host name.
mail.smtp.port	25	Port number used by your mail server.
mail.from	<pre><currentuser>@<curr enthost=""></curr></currentuser></pre>	Email address to use for the From field in the notification email.

The following is an example of a target mesh configuration file that contains only essential mesh configuration information.

twist.host=twist.c07.dev.opsware.com

twist.port=1032

twist.protocol=t3s

twist.username=<detuser>

twist.password=<twist\_password>

twist.certPaths=<absolute path to opsware-ca.crt>

```
spike.username=<OCC_user>
spike.password=<OCC_user_password>
spike.host=way.c07.dev.opsware.com
way.host=way.c07.dev.opsware.com
spin.host=spin.c07.dev.opsware.com
word.host=theword.c07.dev.opsware.com
ssl.keyPairs=<absolute path to spog.pkcs8>
ssl.trustCerts=<absolute path to opsware-ca.crt>
mail.transport.protocol=smtp
mail.smtp.host=mail
mail.smtp.port=44
mail.from=joe_user@yourcompany.com
```

## **Distribution Directory**

# 2 DET Usage

## DCML Exchange Tool (DET) Usage

## **Exporting Content**

DET exports the content you specify from a target SA mesh to an RDF/XML file that can be imported by DET into another SA mesh.

The DET executable is found in the directory:

```
/opt/opsware/cbt/
```

The export command is:

```
cbt -e <content dir> -f <filter file> -cf <target core config>
```

The command and its arguments indicate:

- content\_dir the path to a directory where the exported content will be stored. This directory will be created by the export function if it does not already exist.
- filter\_file a set of rules that tells DET what content it should export from the target SA mesh. See the Export Filters on page 20 for information on creating this file.
- target\_core\_config a configuration file that tells DET where the various SA components are located, and what identity it should use to access them. Instructions for creating this file are found at Creating a Target Mesh Configuration File on page 13.

The export command can be run multiple times using the same arguments, with the following caveats:

- If a filter has been specified, DET will ignore any previous exports in the content directory and will restart the export process.
- If the export command specifies a content directory that contains a valid export (one which previously succeeded), DET will prompt the user if it is OK to overwrite. If the user says it is not OK to overwrite, then DET will exit.

Before beginning an export or import process in a standalone mesh, shut down the Command Center core component to prevent users from changing any SA content until the process has completed.

In a multimaster mesh, first use the multimaster tools to ensure that the mesh is caught up and there are no conflicts, then shut down all Command Centers in the mesh to prevent users from changing any SA content until the process has completed.

See the *SA Administration Guide* for information about stopping and restarting the Command Center core component.

## **Export Filters**

An export filter is a user-specified rule that tells DET what content to export — content that will subsequently be imported. Export filters are used with the following content types:

- Application Export Filter on page 21
- Application Configuration Export Filter on page 23
- Application Configuration Template Export Filter on page 24
- Audit Filter on page 25
- Custom Extension Export Filter on page 25
- Custom Fields Schema Export Filter on page 26
- Customer Export Filter on page 26
- Distributed Script Export Filter on page 27
- Folder Export Filter on page 28
- OS Export Filter on page 30
- Package Export Filter on page 30
- Patch Export Filter on page 32
- Patch Policy Export Filter on page 34
- Server Compliance Criteria (Audit Policies) Export Filter on page 35
- Server (Device) Group Export Filter on page 36
- Service Level Export Filter on page 38
- Snapshot Filter on page 39
- Template Export Filter on page 40
- User Group Export Filter on page 41

To export folder content such as software policies and OS sequences, you export the parent folder using the Folder Export Filter.

### Example: Export Filter File

DET reads export filters in a specified filter file. The filter file is encoded in RDF/XML. The following is an example of a simple filter file that contains a single export filter rule.

This example shows the standard filter headers in lines 1 through 6. These lines are the same in every filter, as is Line 11, which is the standard filter footer.

Lines 7 through 10 are the lines that are unique in each filter and indicate the specific function of the filter.

In the example above, there is just one export filter rule. However, filters can contain any number of unique filters between the standard header and footer lines. For example, this filter contains three export filter rules:

```
<?xml version="1.0" encoding="UTF-8"?>
   <!DOCTYPE rdf:RDF [</pre>
   <!ENTITY filter "http://www.opsware.com/ns/cbt/0.1/filter#">
4.
   <rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
5.
             xmlns="http://www.opsware.com/ns/cbt/0.1/filter#">
6.
7.
   <ApplicationFilter rdf:ID="exportAppServers">
      <path>/Application Servers/Package Test</path>
9.
      <directive rdf:resource="&filter;Descendants" />
10. </ApplicationFilter>
11. <applicationFilter rdf:ID="exportAppServfoo">
      <path>/Application Servers/Foo</path>
12.
13.
      <directive rdf:resource="&filter;Node"/>
14. </ApplicationFilter>
15. <CustomExtensionFilter rdf:ID="exportCustExtBulkPasswd">
      <scriptName>Bulk Password Changes</scriptName>
17. </CustomExtensionFilter>
18. </rdf:RDF>
```

Example filters can be found in the DET install directory under:

```
<install_dir>/filters
```

This directory includes examples for each filter type and also an all.rdf filter, that exports all known SA data types from an SA mesh.

The following sections describe each filter type and their allowed parameters. In general, filter types map to an object type that can be manipulated by a user of the SA Web Client. The Patch Filter, for example, maps to the SA Web Client Patch object. Naming of the filters and their attributes also maps to the naming structure of the SA Web Client so filter authors can quickly acquaint themselves with filters and their relevance to SA content.

### **Application Export Filter**

An application export filter tells DET what application nodes and associated content to export. The following application nodes are shown in the SA Web Client by clicking the Software link in the navigation panel followed by the Application link on the Software menu.

- Application Servers
- Database Servers
- OS Extras
- Other Applications
- System Utilities
- Web Servers

The following tables describe the syntax of the Application Filter element:

**Table 2** Application Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 3** Application Export Filter Nested Elements

Element Description		
path (required)	An absolute path from the top level of the software tree to the node to be exported. The path separator is "/".	
directive (required)	An empty content element with a single rdf:resource parameter. The parameter refers to one of three constants:	
	• Descendants — export all descendants of the given path including the leaf of the path.	
	Node — only export the given node.	
	Path - export all nodes along the path and no other nodes.	
	For example, given the following path:	
	/Custom Applications/A/B/C/D and your path is /Custom Applications/A/B	
	If the rdf:resource parameter is Node, node B is exported.	
	If the rdf:resource parameter is Path, nodes A and B are exported.	
	If the rdf:resource parameter is Descendants, nodes B, C, and D are exported.	
customerName (optional)	This optional element restricts the export to nodes owned by this customer at or below the specified path. If the node specified by the path is not owned by the specified customer, nothing is exported and a warning is logged.	
	For examples of how this element works in a filter file, see customerName Element Examples on page 42.	

## **Application Export Filter Examples**

Export the /Application Servers/Foo node only.

```
<ApplicationFilter rdf:ID="exportAppServfoo">
   <path>/Application Servers/Foo</path>
   <directive rdf:resource="&filter;Node"/>
   </ApplicationFilter>
```

Export Bar and Baz nodes along the given path. (Note that the stack root is not exported.)

<ApplicationFilter rdf:ID="exportDBServBarBaz">

```
<path>/DBServer/Bar/Baz</path>
  <directive rdf:resource="&filter;Path"/>
</ApplicationFilter>
```

Export the patchtool node and all its descendants, including the leaf node.

```
<ApplicationFilter rdf:ID="exportSUpatchtool">
  <path>/System Utilities/patchtool</path>
  <directive rdf:resource="&filter;Descendants"/>
</ApplicationFilter>
```

#### Export all Apache web servers that belong to the Acme customer:

```
<ApplicationFilter rdf:ID="exportAcmeAppServApache">
  <path>/Application Servers/Web Servers/Apache Web</path>
  <directive rdf:resource="&filter;Descendants"/>
  <customerName>Acme</customerName>
</ApplicationFilter>
```

## Application Configuration Export Filter

The Application Configuration export filter tells DET what Application Configurations you want to export. An Application Configuration is a container for one or more Application Configuration Template files. Thus, if you export an Application Configuration, you will also be exporting all template files inside it.

Table 4 Application Configuration Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name"

Table 5 Application Configuration Export Filter Nested Elements

Element	Description
configurationName (optional)	An optional element that specifies the name of the Application Configuration. Use this if you want to export specific Application Configurations by name.
customerName (optional)	An optional element that specifies to export all Application Configurations that have been associated with the specified customer.
osPlatform rdf:resource (optional)	An optional element that specifies to export all Application Configurations that have been associated with the specified OS.

#### Application Configuration Export Filter Example

Export all Application Configurations.

```
<ApplicationConfigurationFilter rdf:ID="getAllAppConfigs"/>
```

Export only the Application Configuration named "iPlanet" that is customer independent and that has been associated with the SunOS 5.8 operating system.

## **Application Configuration Template Export Filter**

The Application Configuration Template export filter tells DET what Application Configuration Template files you want to export.

**Table 6** Application Configuration Template Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name"

 Table 7
 Application Configuration Template Export Filter Nested Elements

Element	Description
configurationFileName (optional)	An optional element that specifies the name of the Application Configuration Template. Use this if you want to export specific Application Configuration Templates by name.
osPlatform rdf:resource (optional)	An optional element that specifies to export all Application Configurations that have been associated with the specified OS.
customerName (optional)	An optional element that specifies to export all Application Configuration Templates that have been associated with the specified customer.

#### Application Configuration Template Export Filter Examples

Export all Application Configuration Templates.

```
<ApplicationConfigurationFileFilter rdf:ID="getAllAppConfigTemps"/>
```

Export the specific Application Configuration Template named "iplanet6.1\_mimetypes.tpl" that is customer independent and is associated with the Red Hat Enterprise Linux AS 3 X86\_64 operating system.

<ApplicationConfigurationFileFilter rdf:ID="getSpecificAppConfigTemp">

<configurationFileName>iplanet6.1 mimetypes.tpl</configurationFileName>

<customerName>Customer Independent

```
<osPlatform rdf:resource="&filter;Red_Hat_Enterprise_Linux_AS_3_X86_64"/>
</ApplicationConfigurationFileFilter>
```

### **Audit Filter**

The audit filter tells DET which audit to export from an SA core/mesh so that you can then import it into another SA core/mesh.

**Table 8** Audit Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 9** Audit Filter Nested Elements

Element	Description
auditPolicyName	The name of the audit policy that you want to export.

#### Example:

## **Custom Extension Export Filter**

The custom extension export filter tells DET to either export a specific custom extension or all custom extensions. If you want to export more than one custom extension, but not all, create a filter for each custom extension you want to export.

**Table 10 Custom Extension Export Filter Parameters** 

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 11 Custom Extension Export Filter Nested Elements** 

Element	Description
scriptName (optional)	An optional element that specifies a script to export. The script name does not include the account prefix. If this element is omitted, all custom extension scripts are exported.

#### Custom Extension Export Filter Examples

Export the Bulk\_Password\_Changes custom extension script only.

#### Export all custom extension scripts.

<CustomExtensionFilter rdf:ID="exportAllCustExtScripts"/>

## Custom Fields Schema Export Filter

The custom fields schema export filter tells DET to export all custom fields definitions from a mesh.

Table 12 Custom Fields Schema Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

### Custom Field Schema Export Filter Example

Export all custom field definitions from a mesh:

<CustomFieldSchemaFilter rdf:ID="getCustomFieldsSchema"/>

## Customer Export Filter

The customer export filter tells DET to export all or specific customers from a mesh.

**Table 13 Customer Export Filter Parameters** 

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 14 Customer Export Filter Nested Elements** 

Element	Description
customerName (optional)	An optional element that specifies a unique customer to export.

#### Customer Export Filter Example

#### Export the all customers from a mesh:

```
<CustomerFilter rdf:ID="exportAllCustomers"/>
```

#### Export Customer named "Acme Computers" from a mesh:

```
<CustomerFilter rdf:ID="exportAcmeCustomer">
    <customerName>Acme Computers</customerName>
</CustomerFilter>
```

## Distributed Script Export Filter

The distributed export script filter tells DET to either export a specific distributed script or all distributed scripts. Only shared distributed scripts are exported and imported.

Table 15 Distributed Script Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name"

#### Table 16 Distributed Script Export Filter Nested Elements

Element	Description
scriptName (optional)	An optional element that specifies a script to export. The script name does not include theglobal prefix. If this element is omitted, all shared distributed scripts are exported.

## Distributed Script Export Filter Examples

#### Export all shared distributed scripts.

```
<DistributedScriptFilter rdf:ID="exportAllSharedScripts"/>
```

#### Export the shared ls distributed script only.

## Folder Export Filter

The folder filter tells DET to either export a specific Folder, including the following items that are associated with or contained in the Folder:

- Attributes and custom attributes
- Associated customers
- Contained packages
- Contained software policies
- Contained OS sequences
- Subfolders (optional)
- Placeholders for all folders along the path to the specified Folder
- FolderACLs referencing user groups by name (user groups not exported).

**Table 17 Folder Export Filter Parameters** 

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name"	

**Table 18 Folder Export Filter Nested Elements** 

Element	Description	
path (required)	A required element that specifies the folder path.	
customerName (optional)	An optional element that restricts the export to folders owned by this customer at or below the specified path. Folder ownership above the specified path is not considered.	
recursive (optional)	An optional element that specifies the export of sub-folders.	

### Folder Export Filter Examples

If the folder specified by the path is not owned by the specified customer, nothing is exported and a warning is logged. If an invalid customer name is given, an error is logged and the export will exit.

For example, suppose that HP Server Automation has the following folder hierarchy. The customer of each folder is listed in parentheses.

```
/ (Customer Independent)
/A (Customer Independent)
/A/B (Customer Independent)
/A/B/C (Nike & Adidas)
/A/B/C/D (Nike)
```

The following examples list which folders are exported given the preceding folder hierarchy and customers.

## Export folder C: <FolderFilter rdf:ID="f1"> <path>/A/C</path> </FolderFilter> Export folder C: <FolderFilter rdf:ID="f1"> <path>/A/C</path> <recursive rdf:resource="&filter;No"/> </FolderFilter> Export folders C and D: <FolderFilter rdf:ID="f1"> <path>/A/C</path> <recursive rdf:resource="&filter;Yes"/> </FolderFilter> Export folders A and B: <FolderFilter rdf:ID="f1"> <path>/A</path> <recursive rdf:resource="&filter;Yes"/> <customerName>Customer Independent/customerName> </FolderFilter> Export folders C and D: <FolderFilter rdf:ID="f1"> <path>/A/C</path> <recursive rdf:resource="&filter;Yes"/> <customerName>Nike</customerName> </FolderFilter> Export folder C: <FolderFilter rdf:ID="f1"> <path>/A/C</path> <recursive rdf:resource="&filter;Yes"/> <customerName>Adidas </FolderFilter>

Export nothing:

<FolderFilter rdf:ID="f1">

<recursive rdf:resource="&filter;Yes"/>

<customerName>Nike</customerName>

<path>/A</path>

</FolderFilter>

## **OS Export Filter**

The Operating System export filter tells DET what Operating System node or Operating System type to export.

**Table 19 OS Export Filter Parameters** 

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".	

#### **Table 20 OS Export Filter Nested Elements**

Element	Description
osName (optional)	The name of the OS assigned by the user in the SAS Web Client.
osPlatform (required)	A required nested element. This empty element has an rdf:resource parameter. This parameter may refer to one of the supported operating systems listed in the SA Supported Platforms documentation.

#### OS Export Filter Examples

Export the "7.1 for mwp" Red Hat Linux 7.1 OS.

```
<OSFilter rdf:ID="exportOSRHLinux71">
  <osPlatform rdf:resource="&filter;Red_Hat_Linux_7.1"/>
  <osName>7.1 for mwp</osName>
</OSFilter>Export all Solaris 5.6 operating systems.
<OSFilter rdf:ID="exportOSSun56">
  <osPlatform rdf:resource="&filter;SunOS_5.6"/>
</OSFilter>
```

## Package Export Filter

The package export filter tells DET to export all or specified packages from a mesh. A placeholder for the containing folder is exported. Placeholders for all folders on the path to the containing folder are also exported.

For Microsoft Hotfixes and service packs, it is possible that the Microsoft package you want to export has not yet had its binary file uploaded, even though the package shows as existing in the mesh. For example, a user may have uploaded the Microsoft Patch Database to the mesh, but not yet uploaded the actual binary file of the package In this case, a unit record for the

package will have been created in the SA model, but there is no content to export. In this case, if you try to export the package content using the Package Export Filter, the content of the Microsoft package will not be exported.

**Table 21 Package Export Filter Parameters** 

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".	

**Table 22 Package Export Filter Nested Elements** 

Element	Description	
packageType (required)	A required element that specifies the package type you want to export. This parameter may refer to one of the following package types:	
	<ul> <li>AIX_Base_Fileset</li> <li>AIX_Update_Fileset</li> <li>APAR</li> <li>Build_Customization_Script</li> <li>HPUX_Depot</li> <li>HPUX_Fileset</li> <li>HPUX_Patch_Fileset</li> <li>HPUX_Patch_Product</li> <li>HPUX_Product</li> <li>Relocatable_ZIP</li> <li>RPM</li> <li>Solaris_Package</li> <li>Solaris_Package_Instance</li> <li>Solaris_Patch_Cluster</li> <li>Unknown</li> <li>Windows_Hotfix</li> <li>Windows_MSI</li> <li>Windows_ZIP (deprecated)</li> <li>ZIP</li> </ul>	
packageName (optional)	An optional element that allows you to specify a named package. The name of the package is the Name field as it appears in the Package Properties page in the SAS Web Client, not the filename of the package.	
osPlatform (optional)	An optional element that allows you to specify the operating system of a named package. This parameter may refer to one of the supported operating systems listed in the <i>SA Supported Platforms</i> documentation.	
customerName (optional)	An optional element that allows you to specify the customer of a named package.	

#### Package Export Filter Example

Export all RPM packages for all servers that are customer independent and that run on the SunOS\_5.8 operating system:

Export the RPM package named "software1.0.0-1.rpm" for all servers that belong to the Acme Computers customer:

A relocatable ZIP file can be installed into different locations on a single server. Because the name of a relocatable ZIP file is the same as that of its parent ZIP file , specifying one will export all relocatable versions of that ZIP file. For example, suppose the ZIP file hierarchy is as follows:

- ZIP hmp.zip (SunOS 5.8)
  - Relocatable ZIP hmp.zip installed in /foo.
  - Relocatable ZIP hmp.zip installed in /bar.

For the preceding ZIP file hierarchy, with the following filter, both relocatable ZIP files will be exported (/foo and /bar).

```
<PackageFilter rdf:ID="p1">
        <packageType rdf:resource="&filter;Relocatable_ZIP"/>
        <packageName>hmp.zip</packageName>
        <osPlatform rdf:resource="&filter;SunOS_5.8"/>
        </PackageFilter>
```

## Patch Export Filter

The patch export filter tells DET what patch or patch type to export.

For Windows patch content that was defined previous to DET 2.5, make sure that the Windows MBSA patch definitions are the same for both the source mesh and the destination mesh, or undefined Windows patches will not get imported.

**Table 23 Patch Export Filter Parameters** 

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 24 Patch Filter Nested Elements** 

Element	Description	
patchType (required)	A required nested element. This empty element has an rdf:resource parameter. This parameter may refer to one of the following patch types:	
	<ul> <li>APAR</li> <li>APAR_FILESET</li> <li>UPDATE_FILESET</li> <li>AIX_Update_Fileset</li> <li>HPUX_PATCH_PRODUCT</li> <li>HPUX_Patch_Product</li> <li>HPUX_PATCH_FILESET</li> <li>HPUX_Patch_Fileset</li> <li>SOL_PATCH</li> <li>Solaris_Patch</li> <li>SOL_PATCH_CLUSTER</li> <li>Solaris_Patch_Cluster</li> <li>HOTFIX</li> <li>Windows_Hotfix</li> <li>SERVICE_PACK</li> <li>Windows_OS_Service_Pack</li> <li>PATCH_META_DATA</li> <li>Microsoft Patch Database</li> </ul>	
patchName (optional)	An optional element that specifies the name of a specific patch. The name must be the patch unit_name, which is the name shown in the SAS Web Client.	
patchLocale (optional)	The locale, which identifies the language of the Windows patch. This element is ignored for non-Windows patches.  Examples of values for this element are en, ja, and ko. These values represent English, Japanese, and Korean. English is the default. For the list of locales currently supported by Windows patching, see the SA User Guide: Patching Servers.	

## Patch Filter Examples

#### Export the IY13260 APAR.

```
<PatchFilter rdf:ID="exportAPARIY13260">
  <patchName>IY13260</patchName>
  <patchType rdf:resource="&filter;APAR"/>
</PatchFilter>
```

#### Export all Solaris patches.

```
<PatchFilter rdf:ID="exportSolPatches">
  <patchType rdf:resource="&filter;SOL_PATCH"/>
  </PatchFilter>
```

#### Export the patch named Q123456 for the Japanese locale.

```
<PatchFilter rdf:ID="pf1">
<patchName>Q123456</patchName>
```

```
<patchLocale>ja</patchLocale>
</PatchFilter>
```

## Patch Policy Export Filter

The patch policy export filter tells DET what user-defined patch policy to export. (Vendor recommended policies will not be exported.)

The optional nested elements <patchPolicyName> and <osPlatform> can be specified to filter for a specific patch policy. If no optional nested elements are specified, all patch policies in the target mesh are exported.

**Table 25 Patch Policy Export Filter Parameters** 

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".	

**Table 26 Patch Policy Export Filter Nested Elements** 

Element	Description	
patchPolicyName	An optional element that specifies the unique name of the patch policy.	
osPlatform	An optional element that specifies a specific operating system of the patch policy using an rdf:resource parameter. This parameter can refer to one of the following operating systems:  • Windows_2000 • Windows_2003 • Windows_NT_4.0	

### Patch Policy Export Filter Examples

Export all patch policies from the target mesh:

```
<PatchPolicyFilter rdf:ID="PatchPolicies"/>
```

Export only the patch policies named "BestWindowsPoliciesNT" on the Windows NT operating system, and "BestWindowsPolicies2003" on the Windows 2003 operating system:

```
<PatchPolicyFilter rdf:ID="PatchPolicies"/>
   <patchPolicyName>BestWindowsPoliciesNT</patchPolicyName>
   <osPlatform rdf:resource="&filter;Windows_NT/>
   </PatchPolicyFilter>

<PatchPolicyFilter rdf:ID="PatchPolicies2"/>
   <patchPolicyName>BestWindowsPolicies2003</patchPolicyName>
   <osPlatform rdf:resource="&filter;Windows_2003"/>
   </PatchPolicyFilter>
```

#### Export all Patch Policies for the Windows 2003 operating system:

```
<PatchPolicyFilter rdf:ID="PatchPolicies"/>
    <osPlatform rdf:resource="&filter;Windows_2003"/>
</PatchPolicyFilter>
```

## Server Compliance Criteria (Audit Policies) Export Filter

The Server Compliance Criteria export filter instructs DET what Audit Policies you want to export.

 Table 27
 Server Compliance Criteria Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name"

**Table 28** Server Compliance Criteria Filter Nested Elements

Element	Description
selectionCriteriaNam (optional)	An optional element that specifies the name of the Audit Policy. Use this if you want to export specific Audit Policy by name.
osType rdf:resource (optional)	An optional element that specifies to export all Audit Policy that have been associated with the specified OS. The two possible values for this element are either Windows or Unix. For example,
	<pre><ostype rdf:resource="&amp;filter;Windows"></ostype></pre>
	or
	<pre><ostype rdf:resource="&amp;filter;Unix"></ostype></pre>

## Server Compliance Criteria Export Filter Examples

Export all Audit Policies.

```
<ComplianceSelectionCriteriaFilter rdf:ID="getAllSelectionCriteria"/>
```

Export the specific Audit Policy named "My Audit Policy" that has been associated with the Windows operating system.

```
<ComplianceSelectionCriteriaFilter rdf:ID="getSpecificSelectionCriteria">
    <selectionCriteriaName>My Audit Policy</selectionCriteriaName>
    <osType rdf:resource="&filter;Windows"/>
    </ComplianceSelectionCriteriaFilter>
```

## Server (Device) Group Export Filter

The server groups export filter tells DET to export specified server groups from a mesh.

 Table 29
 Server Group Export Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

 Table 30
 Server Group Filter Nested Elements

Element	Description
path (required)	A required element that specifies the name of the server group to export.
directive (required)	A required empty content element with a single rdf:resource parameter. Allows you to specify the contents of the groups to export. The parameter refers to one of three constants:
	Node: Exports only the leaf node of the path, but create empty placeholders (name and description, no rules) down the path if the path doesn't already exist.
	Path: Exports all groups along the path (name, description, and rules) but not the descendants.
	• Descendants: Exports all descendants of the given path, including the leaf node of the path.
	For example, given the following path:
	/Group/A/B/C/D and your path is /Group/A/B
	If the rdf:resource parameter is Node, server group node B is exported.
	If the rdf:resource parameter is Path, server group nodes A and B are exported.
	If the rdf:resource parameter is Descendants, server group nodes B, C and D are exported.
customerName (optional)	This optional element restricts the export of attached server group nodes so that only those attached nodes owned by this customer get exported.
	The customerName element does not affect the export of nodes referenced by dynamic server group rules.

#### **Notes**

- Core specific information such as group membership and "Date last used", or History properties, are not exported.
- Static groups can also be exported; however, only the name and description of the group are exported.
- If a dynamic group rule references a custom field, the custom field schema will only export the individual custom field, not the whole schema.
- The path defines whether a group is public or private. So all public groups can be exported by specifying a path of /Group/Public (and Descendants directive).
- Private groups cannot be exported, so a path of /Group/Private will result in an error during export.
- It is possible for an imported dynamic server group to not have any rules. This can happen if the source group only had rules like "Facility is C07" or "Realm is Sat02". Since Facility and Realm are core specific, these rules are not exported.
- Also, any rules that reference Server IDs will not be exported. For example rules like "Server ID equals 55500001" will not be exported.
- All attached software policies are exported.

### Server Group Export Filter Example

Export all public server groups from a mesh:

Export the public server group named "NT Servers" including all sub groups that belong to it:

Export only the public server group named "Production Web Servers" (but none of its subgroups):

Export the public group named "Production Web Servers" and its subgroup named "iPlanet", but no other subgroups.

```
<ServerGroupFilter rdf:ID="exportProdWebServGroupsIP">
  <path>/Group/Public/Production Web Servers/iPlanet</path>
  <directive rdf:resource="&filter;Path"/>
  </ServerGroupFilter>
```

# Service Level Export Filter

The service level export filter tells DET what service level nodes to export.

 Table 31
 Service Level Export Filter Parameters

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".	

**Table 32** Service Level Export Filter Nested Elements

Element	Description	
path (required)	An absolute path from the top level node to the node to be exported. The path separator is "/".	
directive (required)	An empty content element with a single rdf:resource parameter. The parameter refers to one of three constants:	
	Descendants: Export all descendants of the given path including the leaf of the path.	
	Node: Only export the given node.	
	Path: Export all nodes along the path and no other nodes.	
	For example, given the following path:	
	/Service Level/A/B/C/D and your path is /Service Level/A/B	
	If the rdf:resource parameter is Node, node B is exported.	
	If the rdf:resource parameter is Path, nodes A and B are exported.	
	If the rdf:resource parameter is Descendants, nodes B, C and D are exported.	
customerName (optional)	This optional element restricts the export to nodes owned by this customer at or below the specified path. If the node specified by the path is not owned by the specified customer, nothing is exported and a warning is logged.	
	For examples of how this element works in a filter file, see customerName Element Examples on page 42.	

### Service Level Export Examples

Export the /Service Level/Foo node only.

```
<ServiceLevelFilter rdf:ID="exportServLevfoo">
  <path>/Service Level/Foo</path>
  <directive rdf:resource="&filter;Node"/>
  </ServiceLevelFilter>
```

Export Bar and Baz nodes along the given path. Note that the stack root is not exported.

```
<ServiceLevelFilter rdf:ID="exportServLevBarBaz">
  <path>/ServiceLevel/Bar/Baz</path>
  <directive rdf:resource="&filter;Path"/>
</ServiceLevelFilter>
```

Export the Gold Service Level node and all of its descendants, including the leaf node.

```
<ServiceLevelFilter rdf:ID="exportServLevGold">
  <path>/ServiceLevel/Gold</path>
  <directive rdf:resource="&filter;Descendants"/>
</ServiceLevelFilter>
```

### **Snapshot Filter**

The snapshot filter tells DET which snapshot you want to export from an SA core/mesh so that you can then import it into another SA core/mesh.

**Table 33** Snapshot Filter Parameters

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

#### **Table 34 Snapshot Filter Nested Elements**

Element	Description	
snapshotResultId	The ID of the snapshot to export. Snapshot names are <i>not</i> unique such that an ID must be given instead. The ID is shown in the user interface by opening up the Snapshot browser, where it is displayed on the first screen.	

#### Example:

# Template Export Filter

The template export filter tells DET what template nodes to export.

**Table 35 Template Export Filter Parameters** 

Parameter	Description
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf:ID="unique name".

**Table 36 Template Export Filter Nested Elements** 

Element	Description		
path (required)	An absolute path from the top level node to the node to be exported. The path separator is "/".		
directive (required)	An empty content element with a single rdf:resource parameter. The parameter refers to one of three constants:		
	<ul> <li>Descendants - export all descendants of the given path including the leaf of the path.</li> </ul>		
	Node - only export the given node.		
	Path - export all node along the path and no other nodes.		
	For example, given the following path:		
	/Templates/A/B/C/D and your path is /Templates/A/B		
	If the rdf:resource parameter is Node, node B is exported.		
	If the rdf:resource parameter is Path, nodes A and B are exported.		
	If the rdf:resource parameter is Descendants, nodes B, C, and D are exported.		
customerName (optional)	This optional element restricts the export to nodes owned by this customer at or below the specified path. If the node specified by the path is not owned by the specified customer, nothing is exported and a warning is logged.		
	For examples of how this element works in a filter file, see customerName Element Examples on page 42.		

### **Template Export Filter Examples**

Export the /Templates/Foo node only.

```
<TemplateFilter rdf:ID="exportTemplatesfoo">
    <path>/Templates/Foo</path>
    <directive rdf:resource="&filter;Node"/>
</TemplateFilter>
```

Export Bar and Baz nodes along the given path. Note that the stack root is not exported.

```
<TemplateFilter rdf:ID="exportTemplatesBarBaz">
  <path>/Templates/Bar/Baz</path>
  <directive rdf:resource="&filter;Path"/>
</TemplateFilter>
```

Export the Alpha Template node and all of its descendants, including the leaf node.

```
<TemplateFilter rdf:ID="exportTemplatesAlpha">
  <path>/Templates/Alpha</path>
  <directive rdf:resource="&filter;Descendants"/>
</TemplateFilter>
```

### **User Group Export Filter**

The User Group export filter tells DET what user groups to export. A user group export includes the following information for each user group:

- Name
- Description
- The checked state of each feature in the Features tab (of the SAS Web Client user group administration page)
- The checked state of each permission in the Other tab.
- The read, read & write, none state of each role class stack in the Node Stacks tab
- The read, read & write, none state of each customer in the Customers tab
- The read, read & write state of each server group in the Device Groups tab
- The read, read & write, none or yes, no state of each feature in the Client Features tab.

 Table 37
 User Groups Export Filter Parameters

Parameter	Description	
rdf:ID	Each filter has a unique name that is specified in the filter file using the format rdf: ID="unique name"	

Table 38 User Groups Export Filter Nested Elements

Element	Description
groupName (optional)	An optional element that allows you to export specific user groups by name. If groupName is not specified, then all user groups will be exported.

#### Notes

- The membership of users and facility permissions (as seen in the Users and Facilities tabs) are not exported.
- The Customers and Device Groups tabs currently list all customers and server groups respectively to allow the read, read & write, none state to be set. Only customers and device groups that are configured with read or read & write will be exported.

### User Group Export Filter Examples

Export all user groups from a mesh.

```
<UserGroupFilter rdf:ID="exportAllUserGroups"/>
```

Export the group named "SuperUsers":

```
<UserGroupFilter rdf:ID="exportUserGroups">
    <groupName>SuperUsers</groupName>
</UserGroupFilter>
```

Export three user groups with the names "AdvancedUsers," "OpswareAdministrators," and "BasicUsers":

### customerName Element Examples

These examples illustrate how the customerName element works for the Application, Service Level, Template, and Server Group export filters.

This section contains two topics:

- customerName Examples for Applications, Service Levels, Templates
- customerName Examples for Server Groups

#### customerName Examples for Applications, Service Levels, Templates

Given this node hierarchy:

```
Service Levels (owned by Customer Independent)

A (Customer Independent)

B (Customer Independent)

C (Nike & Adidas)

D (Nike)
```

• If your file specifies the following filter definition, then A, B, C, and D will be exported. In other words, the service levels of all customers.

```
<ServiceLevelFilter rdf:ID="a1">
     <path>/Service Level/A</path>
     <directive rdf:resource="&filter;Descendants"/>
</ServiceLevelFilter>
```

• If your file specifies the following filter definition, then A and B will be exported. C and D will be skipped

• If your file specifies the following filter definition, then C and D will be exported.

• If your file specifies the following filter definition, then only C will be exported. D will be skipped because it is not owned by Adidas.

• If your file specifies the following filter definition, then nothing will be exported:

```
<ServiceLevelFilter rdf:ID="a1">
<path>/Service Level/A</path>
<directive rdf:resource="&filter;Descendants"/>
<customerName>Nike</customerName>
</ServiceLevelFilter>
```

### customerName Examples for Server Groups

The examples illustrate how the customerName Element works for the Server Group filter. For example, if your core had this server group hierarchy:

```
Server Groups
Public
SG1
+ /Application Servers/A (owned by Customer
Independent)
+ /System Utilities/B (Nike)
+ /Web Servers/C (Adidas)
```

• If your file specifies the following filter definition, then SG1, A, B, and C will be exported.

• If your file specifies the following filter definition, then SG1 and A will be exported.

• If your file specifies the following filter definition, then SG1 and B will be exported.

If your file specifies the following filter definition, then server group SG1 will be exported.

# Importing Content

The Import process imports content to a target SA mesh.

Content import using the DET into an SA mesh is supported on a forward compatible basis. For example, you can import content from an HP Server Automation 4.7 mesh into an HP Server Automation 5.5 mesh. (But you cannot do this in reverse.)

The DET executable is found in the directory:

```
/opt/opsware/cbt/
```

The import command is:

```
cbt -i <content dir> -p <policy> -cf <target core config> --noop
```

The command and its arguments indicate:

- content dir the directory containing the previously-exported content
- policy the import policy that DET should use when it detects duplicates in the target SA mesh. See the Policy on Importing Content Types on page 45.
- target\_core\_config a configuration file that tells DET where the various SA components are located, and what identity it should use to access them. Instructions for creating this file are located at Installing and Configuring DET on page 12.
- --noop Run the import in a "dry run" mode. In other words, don't modify any data. Instead, output a summary of what changes would be made if run normally.

See Command Syntax on page 57 for a complete list all the available arguments and their meanings.

When Applications are imported using DET, the associated package name in the SA mesh receives a "cbt" suffix. For example:

```
openssh-3.8p1-sol8-sparc-local cbt796213986
```

# Policy on Importing Content Types

The following table shows the affect of the policy you specify on the command-line for each content type when duplicates are found.

#### The choices are:

- overwrite the default if no policy is specified. The effect of this option is different for each content type as described in the table.
- duplicate the effect of this option is different for each content type as described in the following table.
- skip for all content types, specifying "skip" means that if a duplicate is found, a message is entered in the session log and the import continues.

See Command Syntax on page 57 for a complete list of all the available arguments and their meanings.

Table 39 Policies Used By DET When Importing Each Content Type

Content Type	Associated Content Types	Import Policy (Overwrite)	Import Policy (Duplicate)
Application	<ul> <li>Custom attributes</li> <li>Config tracking policy</li> <li>Install order</li> <li>Software list</li> <li>Customer</li> </ul>	Content information overrides existing node in target SA mesh without changing its node ID. Content information is overlaid on the existing node.	Content information is renamed by applying a "cbt- <random>" suffix to the application name.</random>
Application Configuration	Account Application Configuration File	All attributes are updated in overwrite mode.	New Application Configuration is created and named "Oldname- cbt- <random>"</random>
Application Configuration Template	Account	All attributes are updated in overwrite mode.	New Application Configuration template is created and named "Oldname-cbt- <random>"</random>
Config Tracking Policy	NA	Creates and overrides existing policy.	Same as Install Order Relationship.
Custom Attributes	NA	Creates and overrides existing keys. The result is the union of the imported key and existing keys.	Same as Install Order Relationship.
Custom Extension	NA	A new version of the script is created.	Same as overwrite policy.

Table 39 Policies Used By DET When Importing Each Content Type (cont'd)

Content Type	Associated Content Types	Import Policy (Overwrite)	Import Policy (Duplicate)
Custom Field Schema	NA	Display name is the only field that is updated.	Do nothing on duplication.
Customer	NA	Do nothing on duplication.	Do nothing on duplication.
			Please see Synchronizing Multimaster Meshes with Deltas on page 53 for important information about importing customers.
Distributed Script	NA	A new version of the script is created.	Same as overwrite policy.
Folder	<ul> <li>Package</li> <li>Software Policy</li> <li>OS Sequence</li> <li>Customer</li> </ul>	Placeholders for all Folders along the path to this folder are created. All attributes of this folder are updated. Folder contents and associated customers are overlaid on existing data. If folderacls is pecified, folderACLs to any pre- existing user groups are created.	Skip: folders are not duplicated.
Install Hooks	NA	See Unit.	See Unit.
Install Order Relationship	NA	Creates the relationship regardless and override the existing relationship.	Since this is done in the context of the parent node, a new relationship is always created because a parent node is always created - albeit with a different name.
MRL	NA	Always create an MRL in the target mesh using the identical name as in the source mesh.	Same as overwrite.

Table 39 Policies Used By DET When Importing Each Content Type (cont'd)

Content Type	Associated Content Types	Import Policy (Overwrite)	Import Policy (Duplicate)
OS	<ul> <li>Custom attributes</li> <li>Config tracking policy</li> <li>Customer</li> <li>Software list</li> <li>InstallHooks</li> <li>MRL</li> </ul>	Content information overrides existing node in target SA mesh without changing its node ID. Content information is overlaid on the existing node.	Content information is renamed by applying a "cbt- <random>" suffix to the application name.</random>
Package	NA	Package is uploaded over the existing package and will overwrite the "container" package types: LPP, HPUX Depot, and Solaris Package. These package types will be overwritten with the new data if their new contents (contained packages) are a superset of the old contents. If not, DET will revert to the existing "rename" mode.  If the package already exists in a different folder, it is imported as a new package in the new folder the existing package is not moved to the new folder.	Same as overwrite.
Patch	NA	Physical patch package is uploaded and contained units are created in the Software Repository.  AIX LPPs and HPUX Depots, package types will be overwritten with the new data if their new contents (contained packages) are a superset of the old contents. If not, DET will revert to the existing "rename" mode.	Same as overwrite. This is because HP Server Automation cannot reliably and efficiently determine whether a package in the Software Repository is equivalent to the package being uploaded.

Table 39 Policies Used By DET When Importing Each Content Type (cont'd)

Content Type	Associated Content Types	Import Policy (Overwrite)	Import Policy (Duplicate)
Patch Knowledge (PATCH_META _DATA)	NA	The patch database is imported into HP Server Automation, overwriting the existing database, if there is one. The knowledge created by the import will depend on the patch preference settings in the target SA mesh.	Same as overwrite.
Patch Policy	Patch	Description and list of patches are updated.	New patch policy is created and named "Oldname-cbt- <random>"</random>
Server Compliance Criteria	NA	All attributes are updated in overwrite mode.	New Server Compliance Criteria is created and named "Oldname-cbt- <random>"</random>
Server (Device) Group	<ul> <li>Application</li> <li>Software Policy</li> <li>Custom Attribute</li> <li>Custom Field Schema</li> <li>Patch</li> <li>Server Group</li> <li>Service Level</li> </ul>	Group description and type are updated. Dynamic group rules are overwritten. The match "if any rules are met" and "if all rules are met" setting will be updated to reflect what is defined in the export. Custom attributes are overlaid. Attachments to patches, applications and service levels are overwritten.	New server group is created and named "Oldname-cbt- <random>".</random>
Service Level	<ul><li>Custom attributes</li><li>Config tracking policy</li><li>Customer</li></ul>	Content information overrides existing node in target SA mesh without changing its node ID. Content information is overlaid on the existing node.	Content information is renamed by applying a "cbt- <random>" suffix to the template name.</random>
Software List	• Unit	Creates and overrides existing list.	Same as Install Order Relationship.

Table 39 Policies Used By DET When Importing Each Content Type (cont'd)

Content Type	Associated Content Types	Import Policy (Overwrite)	Import Policy (Duplicate)
Template	<ul> <li>Custom attributes</li> <li>Customer</li> <li>Application</li> <li>Patch</li> <li>OS</li> <li>Service Level</li> </ul>	Content information overrides existing node in target SA mesh without changing its node ID. Content information is overlaid on the existing node.	Content information is renamed by applying a "cbt- <random>" suffix to the template name.</random>
Unit	Unit script	Units are associated with a physical package, see Package content type above. Virtual units are always associated with existing units in the target SA mesh - this is presumably created as a side effect of uploading the physical package that is also part of the same import session.	Same as overwrite.
Unit Script	NA	Created and overrides existing unit scripts.	Same as overwrite.
User Group	Customer, Server (Device) Group	User group description is updated. In addition, the checked state of features (as seen in the Features and Other tabs) will be updated to reflect what is in the export. The Read, Read & Write, and None settings of customers, node stacks, and client features will be updated to reflect what is in the export. The Read and Read & Write settings of server groups are updated as well.	New user group is created and named "Oldname-cbt- <random>".</random>

# Import Delete Conditions

If you have specified that content be marked as deleted during an export, running the --delete option on import will delete those marked items from the destination mesh.

In some cases, however, if the content marked for deletion in the destination mesh is being used by parts of the SA model, DET will take a 'no harm' approach by renaming the content item instead of deleting it. Or, if you used the <code>-del</code> option during export but did not use the <code>-del</code> option during import, then any content items marked for deletion in the export will not be deleted in the destination mesh — they will instead be renamed.

When a content item is renamed in the destination mesh, the following naming convention is used for the renamed item:

```
<item name>-cbtDeleted<12345>
```

For example, if Application Configuration "foo" is renamed during one DET run, it would be renamed to "foo-cbtDeleted134234".

Table 40 describes all conditions that must be met for a content item to be deleted on an import, and those cases in which the content item will be renamed. If the conditions for allowing delete are not met, then the item will be renamed according to the renaming convention.

For some content items, there are no restrictions and they will always be marked as deleted when the delete option is used for both import and export. For other content items, deletion will never be allowed.

### Renamed Objects That Cannot Be Found

When a content item is renamed for any reason (no -del or "do no harm"), it may become unfindable by DET on subsequent imports. This reason for this is that the name by which the item is located in the destination mesh has been changed due to the rename.

For example, if Application Configuration "foo" is renamed during one DET run to "foo-cbtDeleted134234", on subsequent runs the DET will attempt and fail to find an Application Configuration named "foo". This will prevent the DET from re-renaming or deleting the Application Configuration.

Types of objects with dependencies that can become unfindable after they get renamed include Application, Application Configuration, Application Configuration file, Compliance Selection Criteria, Custom Extension, Distributed Script, OS, Patch Policy, Server (Device) Group, Service Level, Template.

Table 40 Condition for Content Items to Be Deleted Upon Import with the -del Option

object type	Conditions allowing delete
Application	Zero attached devices.
	Zero child nodes.
	Zero templates or device groups include this node.
Application	In use by zero servers or device Groups.
Configuration	In use by zero software policies.
Application Configuration File	In use by zero application configurations.
Compliance Selection Criteria	Always allow delete.
Custom Extension	Never allow delete; always rename.
Custom Field Schema	Always allow delete.
Customer	Zero application, service level, and template nodes.
	Zero non-deactivated devices.
	Zero packages (including those with status DELETED).
	Zero IP range groups.
	Zero folders.
	Note: A Customer cannot be deleted if it has any packages still in SA, including those with the status DELETED. When an object has a DELETED status, it means that either a) the package is still needed for remediation operations on at least one server, or b) the Satellite Software Repository Cache has not yet flushed the package. If this is the case, then the Customer marked for deletion will not be deleted, but renamed.
Deployment Stage Value	Zero devices using this value.
Disturbed Script	Always allow delete.
Folder	Zero contained packages, software policies, and sub-folders.
OS	Zero attached devices.
	Zero child nodes.
	Zero templates or device Groups include this node.

Table 40 Condition for Content Items to Be Deleted Upon Import with the -del Option (cont'd)

object type	Conditions allowing delete	
Package	Is a deletable unit type (see below)	
	Zero Solaris patch clusters or MRLs use this package.	
	Zero software policies use this package.	
	If a ZIP package, it has zero child relocatable ZIPs.	
	Zero OS definitions or application nodes use this package.	
	Zero software policies use this package.	
	If a patch:	
	<ul> <li>Zero devices attached to the patch node.</li> </ul>	
	<ul> <li>Zero templates or device Groups include the patch node.</li> </ul>	
	<ul> <li>Zero patch policies or patch exceptions include the patch node.</li> <li>If an LPP, HPUX depot, or Solaris package:</li> </ul>	
	<ul> <li>Zero sub-packages in use by software policies.</li> </ul>	
	<ul> <li>Zero OS definitions or application nodes use any sub-package.</li> </ul>	
	— For any sub-package that is a patch:	
	<ul> <li>Zero devices attached to the patch node.</li> </ul>	
	<ul> <li>Zero templates or device Groups include the patch node.</li> </ul>	
	<ul> <li>Zero patch policies or patch exceptions include the patch node.</li> </ul>	
	Deletable package unit types* (see list following this table)	
Patch Policy	Zero attached devices.	
	Zero attached device groups.	
Server (Device)	Zero attached devices.	
Group	Zero child nodes.	
	Not used by access control.	
	Zero dynamically bound jobs.	
Server Use Value	Zero devices using this value.	
Service Level	Zero attached devices.	
	Zero child nodes.	
	Zero templates or device Groups include this node.	
Template	Zero child nodes.	

<sup>\*</sup> Detectable package unit types:

- PROV\_INSTALL\_HOOKS
- RPM
- SERVICE PACK
- SOL\_PATCH
- SOL PATCH CLUSTER
- SOL PKG
- SP\_RESPONSE\_FILE
- UNKNOWN
- UPDATE ROLLUP
- WINDOWS\_UTILITY
- ZIP

# Considerations When Importing Customers

Currently, DET does not support the export of user group permissions that are associated with customers, except in cases when the customer name being exported has the same name as a customer in the target mesh (the mesh you are importing the customer into).

For example, let's say that in your source mesh, you had a software application node named iPlanet, and that software application node iPlanet was accessible for reading and writing to all groups associated with a customer named Computing Machines. One of these groups associated with the customer Computing Machines was named groupA.

Next, you export a software application node iPlanet from the source mesh, and then import that node into a new mesh — and this mesh does not have a customer named Computing Machines. The result would be that any users in groupA would not be able to see software application node iPlanet in the target mesh.

However, if the mesh you imported the customer Computing Machines into already has a customer with exactly the same name, then all permissions are untouched in the new mesh and all users group would be able to access the software application node named iPlanet — in other words, all permissions associated with the Computing Machines customer (the ability to read and write the software node iPlanet) will remain in tact.

### Importing Customers Workaround

If a user group loses permissions to access objects (such as servers associated with a customer), then use the SAS Web Client to re-assign the permissions. Until doing so, only users who are administrators will see these customers and their associated objects.

# Synchronizing Multimaster Meshes with Deltas

This release of DET provides the means of performing 'incremental" exports and imports, which helps you keep the content in your multimaster mesh synchronized and up to date.

For example, you can run regular exports from your "source" mesh that represents all the content you want other meshes to contain. Using the new options allows you to export only content that has been modified or deleted so that your target mesh are consistent with the source mesh.

### **Delta Exports**

These command-line options allow you to perform an delta export:

• --baseline (short form: -b)

Specifies a baseline export against which to compare the current export. This requires that either --incremental or --delete be specified during export.

--incremental (short form: -incr)

Of the content specified by the filter file, export only that which has been added or modified since the baseline. If this option is not given, all content specified by the filter file is exported. Must be used with --baseline.

--delete (short form: -del)

Include in the export any content in the baseline that is not specified by the filter file, marked "as deleted". If this option is not given, nothing is exported "as deleted". Must be used with --baseline.

Here is what happens when you use --delete and --incremental in combination with -- baseline during an export:

No incremental export options.

All content specified by filter file is exported.

• -incr

All content specified by filter file that is new or changed since the baseline is exported.

• -del

All content specified by filter file is exported (since -incr is not given), plus all content in the baseline that is not specified by the filter file ("as deleted").

-incr -del

All content specified by filter file that is new or changed since the baseline is exported, plus all content in the baseline that's not specified by the filter file ("as deleted").

### **Delta Imports**

This command-line options allows you to perform a delta import (if certain options were given during export):

• --delete (short form: -del)

If the --baseline option was given with --delete during export, then using the --delete option during import will delete objects that have been marked for deletion from the export.

If the --baseline option was given with --delete during export, but you do not use --delete during import, the items marked for deletion will not be deleted but rather renamed. For more information on cases in which some content may never get deleted and always renamed (for example, if the object has a dependency elsewhere in the mesh) then see Import Delete Conditions on page 50.

### Mesh Synchronization Usage Scenario

Here is what a typical incremental export and import cycle might look like when content in the source mesh has been both deleted and modified:

• Initial, full export of a filter that exports Application Configuration content:

```
cbt -e content/appConfig.0 -f ac Filter.rdf -cf meshA Config
```

• Import exported content into another mesh:

```
cbt -i content/appConfig.0 -p overwrite -cf meshB Config
```

Content is changed and deleted in source mesh.

• Export the modified and deleted content from the source mesh using -b and -incr and - del:

```
cbt -e content/appConfig.1 -f ac_Filter.rdf -b content/appConfig.0 -incr -
del -cf meshA Config
```

• Import the delta into the destination mesh, updating the modified content and deleting the deleted content:

```
cbt -i content/appConfig.1 -p overwrite -cf meshB_Config -del
```

- Repeat steps four and five every time you want to update content, using the most recent export as your baseline. For example, on the next round you would use:
  - Export content/appConfig.2 with -b content/appConfig.1.
  - Import content/appConfig.2.

## Content Directory

The content directory is the persistent store of exported SA content. The content directory contains:

- data.rdf a database of exported SA configuration content.
- filter.rdf a database of filters provided by the user and generated by DET.
- blob/ a directory containing exported software packages and scripts.
- var/ a directory containing logs for each of the last ten import and export sessions. Logs are named <code>cbtexport {0-9}.log</code> and <code>cbtimport {0-9}.log</code>. The 0 log is always the most recent and the 9 log file is always the oldest of the ten session logs.

### The following is an example content directory.

```
% ls -R
.:
blob
data.rdf
filter.rdf
var

./blob:
unitid_140270007.pkg
unitid_166510007.pkg
unitid_166540007.pkg
unitid_2090007.pkg
var:
cbtexport0.log
cbtexport0.log.lck
cbtimport0.log
```

# 3 DET Commands

The DET command line is pre-configured to be executed as the user root on a managed server. If used in this configuration, you will only have to provide your SA user name and password to perform an export or an import. The following is an example session: (The example below assumes the user has been granted import and export permission. For more information, see Installing and Configuring DET on page 12.)

The following is an example csh session on the Command Center server.

```
% setenv JAVA_HOME <j2re 1.4.x installation>
% <cbt install dir>/bin/cbt -e /tmp/foo -f \
<cbt install dir>/filters/app.rdf \
--spike.username hermaime
Enter password for hermaime: *******
```

# **Command Syntax**

The following sections describe the syntax of the DET command line interface.

### **Export Command**

The export command uses the following syntax:

```
cbt -e <content_dir> [<options>]
```

**Table 41 Export Command Options** 

<b>Short Option</b>	long option	description
-e <content_dir></content_dir>	export <content_dir></content_dir>	Export SA data from an SA core and store the data in the given content directory.
-f <filter_file></filter_file>	filter <filter_file></filter_file>	The first time you export, you must specify a filter file describing what data to export. After that, if no filter is specified, then any previously-used filter in the content directory is used. For more information on the DET filter file, see Example: Export Filter File on page 20.

Table 41 Export Command Options (cont'd)

Short Option	long option	description
-b <content_dir></content_dir>	baseline <content_dir></content_dir>	Specifies a baseline export against which to compare the current export. This requires that eitherincremental ordelete be specified during export.
-incr	incremental	Performs an incremental export. Of the content specified by the filter file, export only that which has been added or modified since the baseline. If this option is not given, all content specified by the filter file is exported.
-cf <file></file>	config <file></file>	Specifies the DET configuration file. For more information, see Creating a Target Mesh Configuration File on page 13.
-c	clean	Remove previously exported data from the content directory given by -e.
-d	debug	Show more detailed debug information.
-del	delete	Include in the export any content in the baseline that's not specified by the filter file, marked "as deleted". If this option is not given, nothing is exported "as deleted".  If used, baseline  must also be used to specify the baseline export.
-np	noprogress	Don't show the progress on the console.
-nd	nodownload	Don't download the units from Software Repository (the word). IMPORTANT: Exports using this option cannot be imported.
-lx	logxml	Create log file in XML format.

Table 41 Export Command Options (cont'd)

Short Option	long option	description
-em	email	Email a summary of the export to this comma-separated list of addresses. In order for this option to work, you must have added the email notification parameters to the DET configuration file.
(none)	emaillog	Include the entire log file in the email.

### Change for -c Option

The -c option can no longer be used on its own and must instead be used with the export command.

For example, previously, you would have cleaned out the content directory using the following command:

```
$ cbt -c <content-dir>
```

Now, the -c (or --clean) flag can only be used with the export command. For example:

```
$ cbt -e <content-dir> -c (or --clean)
```

## Import Command

The import command uses the following syntax:

**Table 42 Import Command Options** 

Short Option	long option	description
-i <content_dir></content_dir>		Import SA data from the given content directory.

DET Commands 59

Table 42 Import Command Options (cont'd)

Short Option	long option	description
-p overwrite duplicate skip	policy overwrite duplicate skip	Import policy. Default is "overwrite."
		"overwrite" means to override objects in the same name space on the target HP Server Automation without affecting its object IDs.
		"duplicate" means to create a duplicate copy of an object with a synthetic name when a duplicate is detected on the target HP Server Automation.
		"skip" is the most conservative policy. It aborts the import of an object if the same object is detected in the target HP Server Automation.
		For more information on import policies for the specific content types, see Policy on Importing Content Types on page 45.
-del	delete	Delete objects marked deleted by the export. (In other words, this option will only work if the -del option was given during export. If this option is not given, the objects will be renamed.

Table 42 Import Command Options (cont'd)

<b>Short Option</b>	long option	description
-fa	folderacls	Associate imported folders with existing user groups.
		If this option is not specified, import the folders with the ACLs inherited from the parent folder in the destination mesh.
		If this option is specified, the DET will attempt to import the ACLs when importing the folder. An ACL will import only if a user group with the same name as in the source mesh already exists or has been imported as part of the current DET run. The ACLs will become associated with the existing user group of the same name. When inserting a folder, the imported ACLs with replace any inherited from a parent folder in the destination mesh. When updating a folder, the ACLs will overlay existing ACLs.
-n	noop	Run the import in a "dry run" mode. In other words, don't modify any data. Instead, output a summary of what changes would be made if run normally.
-cf <file></file>	config <file></file>	Read configuration from the given file.
-d	debug	Show more detailed debug information.
-np	noprogress	Don't show the progress on the console.
-nu	noupload	Don't upload unchanged packages to the Software Repository (the word).
		The utility reports that the package is overwritten, but the package is untouched. Only its unit record is updated.

DET Commands 61

Table 42 Import Command Options (cont'd)

Short Option	long option	description
-lx	logxml	Create log file in XML format.
-em <addrs></addrs>	email <addrs></addrs>	Email a summary of the import to this commaseparated list of addresses. In order for this option to work, you must have added the email notification parameters to the DET configuration file.
(none)	emaillog	Include the entire log file in the email.

## **Show Export Status Command**

The show export status command uses the following syntax:

**Table 43 Show Export Status Command Options** 

short option	Long option	description
-t		Show status of export of the given content directory.

## Configuration File Command

The configuration file command option uses the following syntax:

**Table 44 Configuration File Command Options** 

short option	Long option	description
-s	showconfig	Show current configuration values.
-cf <file></file>	confi <file></file>	Read configuration from the given file.

### **Show Version Command**

The show version command uses the following syntax:

**Table 45 Show Version Command Options** 

short option	Long option	description
-A	version	Show the version of the DET tool.

# Show Help Command

The show help command uses the following options:

cbt -h

**Table 46 Show Help Command Options** 

short option	Long option	description
-h	help	Display this help message.

### **DET Permissions Command**

The DET permissions command uses the following syntax:

```
cbtperm -u [user] -a [spike.username] -p [spike.port] -s [spike.host] -c
[ssl.trustCerts] -k [ssl.keyPairs]
```

**Table 47 DET Permissions Command Options** 

short option	Long option	description
-u	N/A	The user to whom you want to grant permission to use the DCML Exchange Tool.
-a	spike.username	User name for Spike authentication, such as the SA Administrator.
-p	spike.port	Spike's listener port.
-s	spike.host	Spike's hostname or IP.
-c	ssl.trustCerts	Comma-separated list of trust certificate files to be used to communicate with XML-RPC servers
-k	ssl.keyPairs	Comma-separated list of client certificates to be used to communicate with XML-RPC servers

DET Commands 63

# 4 IDK Overview

### Overview of the IDK and ISMs

HP Server Automation includes the Intelligent Software Module (ISM) Development Kit (IDK). The IDK consists of command-line tools and libraries for creating, building, and uploading ISMs. An ISM is a set of files and directories that include application bits, installation scripts, and control scripts. You build an ISM in a local file system and then upload the ISM into an HP Server Automation application policy. After uploading the ISM, you use the HP Server Automation Client to install the ISM's application onto managed servers.

### Benefits of the IDK

The IDK offers the following benefits:

- Encapsulates best practices for managing software products, enabling standards teams to deliver stable and consistent software builds and manage change in complex data center environments.
- Uploads modules into HP Server Automation, making them immediately available for installation onto managed servers.
- Separates an application's installation and control scripts from the bits to be installed. You can update the scripts without having to re-install the application bits.
- Enables dynamic configuration by querying HP Server Automation for custom attributes.
- Automatically builds native packages (such as RPMs) from binary archives.
- Support on Unix platforms for building from source code with a common specification format.
- Provides command-line tools for developers and administrators who prefer building packages and writing installation scripts in a shell environment.

#### **IDK Tools and Environment**

The IDK includes the following:

- ISMTool A command-line tool that creates, builds, and uploads ISMs.
- ISMUserTool A command-line tool that specifies the users allowed to upload ISMs.
- Environment variables Shell environment variables accessed by the ISMTool.
- Runtime libraries The HP Server Automation routines that support the IDK tools.

### Supported Package Types

You can use the IDK to create the following types of packages:

- AIX LPP
- HP-UX Depot
- RPM
- Solaris Package
- Windows MSI
- ZIP (Windows and Unix)

# Installing the IDK

It is recommended that you install and run the IDK on a managed server (a server running a server agent). For instructions, see Installing the IDK on a Managed Server on page 66. For more information on server agents, see the *SA User Guide: Server Automation*.

You can install the IDK on a core server, but do so with care. The core components share the CRYPTO\_PATH environment variable with the IDK tools. If you set the CRYPTO\_PATH environment variable incorrectly, the core components might cease to function.

You can install the IDK on an unmanaged server (a server that does not run a core component or an agent), but the functionality of the IDK will be limited. On such a server, you can build ISMs but you cannot upload them to the core unless you set the CRYPTO\_PATH environment variable. See CRYPTO\_PATH on page 116 for information on this variable. See Installing the IDK on an Unmanaged Server on page 67.

### Installing the IDK on a Managed Server

To install the IDK and the ISMTool on a managed server, perform the following steps:

- 1 Choose a managed server to run the IDK.
- 2 Verify that the host where you install the IDK runs the same operating system version as the managed servers where the ISM's application will be installed.
  - For example, if you are creating ISMs for applications to be installed on Redhat Linux 7.3 managed servers, install the IDK on a Redhat Linux 7.3 system.
- 3 If you are installing the IDK on a Windows managed server, set the CRYPTO\_PATH environment variable as described in CRYPTO\_PATH on page 116.
- 4 If you are installing the IDK on a Redhat Linux Application Server, Enterprise Server, or Workstation, then make sure that the rpm-build package is already installed. To verify that this package is installed, enter the following command:

```
rpm -qa | grep rpm-build
```

5 If you are installing the IDK on a Solaris zone, make sure that the /usr/local directory exists and has write access. (This directory might not exist in a sparse root zone.) You can perform this task either with HP Server Automation or with the following zonecfg commands, where *path* is the file system on the global zone:

```
zonecfg:zone-name:fs> add fs
```

```
zonecfg:zone-name:fs> set dir=/usr/local
zonecfg:zone-name:fs> set special=path
zonecfg:zone-name:fs> set type=lofs
```

- 6 In the SA Client, search for a software policy with a name that contains "ismtool."
- 7 In the list of software policies displayed, right-click the policy for the platform where you will run the IDK, and then select Attach Server.
- 8 On the Attach Server window, select the managed server where you will run the IDK.
- 9 Make sure that the Remediate Servers Immediately check box is selected.
- 10 Click Attach.
- Unix: In a terminal window, log in as root to the host where you are installing the IDK and set the PATH environment variable to include the following value.

```
/usr/local/ismtool/bin
```

(On Windows the PATH is set automatically, but will not take effect until you log in again.)

12 In a terminal window, check the IDK installation by entering the following command:

```
ismtool --myversion
```

### Installing the IDK on an Unmanaged Server

It is recommended that you install and run the IDK on a managed server (a server running a server agent). For instructions, see Installing the IDK on a Managed Server on page 66.

You can install the IDK on an unmanaged server (a server that does not run a core component or an agent), but the functionality of the IDK will be limited. On such a server, you can build ISMs but you cannot upload them to the core unless you set the CRYPTO\_PATH environment variable. See CRYPTO\_PATH on page 116 for information on this variable.

To install the IDK and the ISMTool on an unmanaged server, perform the following steps:

- 1 Choose a managed server to run the IDK.
- 2 Verify that the host where you install the IDK runs the same operating system version as the managed servers where the ISM's application will be installed.
  - For example, if you are creating ISMs for applications to be installed on Redhat Linux 7.3 managed servers, install the IDK on a Redhat Linux 7.3 system.
- If you are installing the IDK on a Windows managed server, set the CRYPTO\_PATH environment variable as described in CRYPTO\_PATH on page 116.
- 4 If you are installing the IDK on a Redhat Linux Application Server, Enterprise Server, or Workstation, then make sure that the rpm-build package is already installed. To verify that this package is installed, enter the following command:

```
rpm -qa | grep rpm-build
```

If you are installing the IDK on a Solaris zone, make sure that the /usr/local directory exists and has write access. (This directory might not exist in a sparse root zone.) You can perform this task either with HP Server Automation or with the following zonecfg commands, where *path* is the file system on the global zone:

```
zonecfg:zone-name:fs> add fs
zonecfg:zone-name:fs> set dir=/usr/local
zonecfg:zone-name:fs> set special=path
```

IDK Overview 67

```
zonecfg:zone-name:fs> set type=lofs
```

- 6 In the SA Client, search for a software policy with a name that contains "ismtool."
- 7 Locate and open the policy that matches the target server platform.
- 8 Select the Policy Items view to see all the packages in the policy.
- 9 Locate and open the package that matches the OS and architecture of the target server.
- 10 Download the package to the target server using the **Actions** ➤ **Export Software** menu.
- 11 Manually install the package onto the target server.
- 12 Unix: In a terminal window, log in as root to the host where you are installing the IDK and set the PATH environment variable to include the following value.

```
/usr/local/ismtool/bin
```

(On Windows the PATH is set automatically, but will not take effect until you log in again.)

13 In a terminal window, check the IDK installation by entering the following command:

```
ismtool --myversion
```

## **IDK Quick Start**

This section shows how to create, build, and upload a simple ISM. After the upload operation, you can run the SA Client and examine the software policy containing the uploaded ISM.

Perform the following steps in a terminal window of the host where you've installed the IDK. Unless otherwise noted, the commands are the same on Unix and Windows.

- 1 Unix: Log in as root to the server where you installed the IDK.
  - If you cannot log in as root, then log in as another Unix user and set the CRYPTO\_PATH environment variable as described in CRYPTO\_PATH on page 116.
- 2 Windows: Open a terminal window and make sure that the CRYPTO\_PATH environment variable is set.
- 3 Grant your user the privilege to upload ISMs by entering the ismusertool command, for example:

```
ismusertool --addUser johndoe
```

This command asks you to confirm that you are contacting the core through an agent gateway:

```
Using an agent gateway to reach an Opsware Core. Is this correct? [y/n]: y
```

Next, the command prompts for the Opsware admin user name and password:

```
Enter Opsware Admin Username: admin Enter admin's Opsware Password:
```

For more information, see ISMUserTool on page 119.

4 Create a new ISM.

For example, to create an ISM named foo, enter the following command:

```
ismtool --new foo
```

This command creates a directory named foo at the current directory level. The ISM is made up of the contents of the foo directory. You'll specify the foo ISM in the subsequent ismtool commands.

5 Add the application files to the ISM.

One way to add the application files is to copy one or more archives to the bar subdirectory. For example, if the application bits are in a file named mytest.zip, you might add them to the ISM as follows:

#### Unix

```
cp /tmp/mytest.zip foo/bar
```

#### Windows:

```
copy c:\temp\mytest.zip foo\bar
```

6 Set the path to the software policy that will contain the ISM you upload in a later step.

Note: You must have Write Objects Within Folder permission to the folder that contains the software policy. Folder permissions are set on the Folder Properties window of the SA Client.

The following ismtool command sets the path to the software policy named Quote Policy:

#### Unix:

```
ismtool --opswpath '/My Kit/Service/Quote Policy' foo
```

#### Windows:

```
ismtool --opswpath "/My Kit/Service/Quote Policy" foo
```

On Unix you enclose the path in single quotes, but on Windows you use double quotes. For both Unix and Windows, the path contains forward slashes.

7 Build the packages within the ISM by entering the following command:

```
ismtool --build foo
```

This command creates three packages in the foo/pkg subdirectory. On a Linux system, these packages are as follows:

```
foo-1.0.0-1.i386.rpm
foo-ism-1.0.0-1.i386.rpm
ismruntime-rpm-3.0.0-1.i386.rpm
```

The foo-1.0.0-1.i386.rpm package contains the application bits, which in this example were copied to the foo/bar subdirectory in step 5. The foo-ism-1.0.0-1.i386.rpm package holds the installation hooks and control scripts. (Because this example is simple, it has no control scripts.) The ismruntime-rpm-3.0.0-1.i386.rpm package contains the SA shared runtimes that the Server Agent will use when it installs the package on a managed server.

Note that the package type (RPM) corresponds to the native packaging engine of a Linux System. On Windows, the --build command creates following MSI packages in the foo\pkg subdirectory:

```
foo-1.0.0-1.msi
foo-ism-1.0.0-1.msi
ismruntime-msi-3.0.0-1.msi
```

8 Upload the ISM into the software policy by entering the following command:

```
ismtool --upload foo
```

IDK Overview 69

This command generates several prompts. First, it asks you to confirm the core into which you are uploading the ISM:

```
Using the following Opsware Core:
```

```
Data Access Engine: d02 192.168.198.91:1004 Software Repository: d02 192.168.198.91:1003 Command Engine: d02 192.168.198.91:1018 Is this correct? [y/n]: y
```

Next, the --upload command prompts for the Opsware user and password:

```
Enter Opsware Username: johndoe
Enter johndoe's Opsware Password:
...
Success!
```

In the SA Client, open the software policy and verify that it contains the ISM you uploaded in the preceding step.

## Platform Differences

In general, the IDK functions the same on packages from different platforms (operating systems). However, there are a few differences, as explained in the following sections.

#### Solaris Differences

Solaris package names have a 9 character limit. By convention, the format is a set of capital letters, followed by a set of lower case letters that identify the application. Optionally, the final character may have a special meaning. Note that this format is a convention, not a requirement. Here are some examples of Solaris package names:

```
SPROcc
SPROcmpl
SPROcodmg
SUNWgssx
SUNWgzip
SUNWhea
SUNWhiu8x
SUNWhmd
SUNWhmdu
SUNWhmdu
```

When the ISMTool creates a Solaris package, it must use a package name that is no more than 9 characters in length. The package name constructed by ISMTool begins with ISM, followed by the five first characters of the ISM's name, followed by the letter c for the control package or a digit 0 for the first part of an application package, 1 for the second part, and so forth. For example, if the ISM name is foobar, the package names would be the following:

```
ISMfooba0
ISMfoobac
```

If truncation occurs, ISMTool generates a warning so that the developer can rename the ISM to avoid naming conflicts. To view the package names, use the Solaris pkginfo command.

If you upload a Solaris passthru package, the response file is not uploaded. You must manually upload the response file.

### Windows Differences

On Windows, when ISMTool creates the application and control Windows Installer (MSI) packages, it encodes the ProductName and ProductVersion as follows:

ProductName: <name>-<version>
ProductVersion: 0.0.<app|ctl release>

The <name>, <version>, and <release> correspond to an ISM's internal information, which can be viewed with the ISMTool's --info command. This encoding scheme is by design and is required for the remediation process to work correctly.

IDK Overview 71

# 5 IDK Build Environment

# ISM File System Structure

The ISMTool --build and --upload commands operate on the ISM directory, which you create with either the --unpack or --new commands. The --unpack command unzips a file (containing the ISM directory contents) that was previously zipped with --pack. The --new command initially creates the ISM directory. For example, the following command creates a new directory named ntp-4.1.2:

```
ismtool --new ntp-4.1.2
```

This command creates the following subdirectories under the ntp-4.1.2 directory:

- bar Contains binary archives, the contents of which are used to create the application package.
- doc A location for documentation (HTML) generated automatically during ISM build. You can also create other documentation files in the directory.
- ism Contains all the files needed to create the control package of the ISM. The ism directory is where you can edit the default package hooks (pre-install, post-install, pre-uninstall, post-uninstall), as well as add control scripts to ism/control.
- log Holds files which keep track of the output from source transformations (compilation or local installs), output from native packaging engines such as msi, rpm, pkgtrans, swpackage, or an SA upload.
- pad Contains the installation scripts (pre-install, post-install, pre-uninstall, post-uninstall) specified by the ISMTool --addPkgProp option.
- pkg Contains the application, control, and shared runtime packages, all of which are generated by --build. This subdirectory also contains copies of passthru packages.
- tmp Used as scratch space for ISMTool operations.
- src May optionally contain files that can control the compilation of sources into binary archives

The following listing shows the contents of the ISM subdirectories after the following command:

```
ismtool --build ntp-4.1.2
```

The output of the source build is in the binary archive directory with the generated name \_\_ntp-4.1.2\_src\_ntp.spec.cpio. The build creates the files in the log, pkg, and tmp subdirectories, in addition to the other files with names beginning with two underscores.

```
_ntp-4.1.2_src_ntp.spec.cpio.meta

                          scripts/
    ntp-ism-4.1.2-7.i386.rpm/
```

# **Build Process**

This section describes the following:

- When to Invoke the --build Command
- Multiple Command-Line Options
- Actions Performed by the --build Command
- Packages Created by the --build Command

### When to Invoke the --build Command

You run the ISMTool --build command after --new and before --upload. Whenever you change an ISM with an option, you must invoke --build before --upload for the change to take effect. For example, if you specify --opswpath, you must invoke --build for the new software policy path to take effect before you upload the ISM.

## Multiple Command-Line Options

You may invoke multiple ISMTool options on the same command-line, or you may invoke the options separately. In the following Unix example, the command changes the native package engine to rpm3, the version to 2.0.47b, the default install user to root, and the default install group to root for the ISM directory named apache:

```
ismtool --pkgengine rpm3 --version 2.0.47b --user root --group root apache
```

The next sequence of commands is equivalent:

```
ismtool --pkgengine rpm3 apache
ismtool --version 2.0.47b apache
ismtool --user root apache
ismtool --group root apache
```

The ISMTool sorts command actions into the proper logical order for execution. The following command, for example, will change the version of apache to 3.0 before the build is executed.

```
ismtool --build --version 3.0 apache
```

# Actions Performed by the --build Command

The ISMTool --build command performs the following steps.

- Performs a pre-build clean by removing all side-effect build products. However, this step will leave any cpio archives generated during a previous build as a form of build cache.
- 2 Runs the optional script ism/build/ism\_clean. The scripts in the ism/build subdirectory are hooks into the build process. To use these scripts, you must create them manually.
- Runs a checksum on the application sources and increment the application release number if the current checksum does not match the previous checksum.
- 4 Runs a checksum on the control sources (the contents of the ism subdirectory) and increment the control release number if the current checksum does not match the previous checksum.
- 5 Runs the optional script ism/build/ism pre.
- 6 For source builds, recursively searches for .spec files in the src subdirectory, compiling and executing each.
- 7 Creates the shared runtime package.
- 8 Creates the control package.
- 9 Creates the application package.
- 10 Generates the automatic HTML document doc/index/index.html.
- 11 Runs the optional script ism/buid/ism-post.

IDK Build Environment 75

## Packages Created by the --build Command

The --build command creates the following packages in the pkg subdirectory:

• Application package - Created from the contents of the bar (binary archive) subdirectory, this package contains the application bits. You copy the application archives to the bar subdirectory before invoking the --build command. The file name of the application package has the following syntax. The <version> is for the entire ISM, and the <release> is specific to the application package. See ISM Name, Version Number, and Release Number on page 80 for more information.

```
<name>-<version>-<release>.<package-extension>
```

• Control package - This package contains the control and installation scripts from the ism subdirectory. The control package file name has the following syntax:

```
<name>-ism-<version>-<release>.<package-extension>
```

• Shared runtime package - This package holds the shared runtime routines that are invoked by the Server Agent (during installation) and by any control scripts. These runtime routines are for HP Server Automation, not for the application itself. The file name of the shared runtime package has the following syntax. (The <ctl-prefix> is included in the file name only if you've specified a non-default value with the --ctlprefix option.)

```
ismruntime-<ctl-prefix>-<package-type>-<idk-version>.<package-extension>
```

• Passthru packages - You specify these packages with the --addPassthruPkg option, which copies them into the pkg subdirectory unchanged.

# Specifying the Application Files of an ISM

This section discusses the methods for getting application files into an ISM:

- Placing Archives in the bar Subdirectory
- Specifying Passthru Packages
- Compiling Source (Unix Only)

# Placing Archives in the bar Subdirectory

Before running --build, you may manually copy file archives to the ISM's bar (binary archive) subdirectory. Alternatively, the archives in the bar subdirectory may be generated as cpio files by the directives in the %files section of the specfile. See also Compiling Source (Unix Only) on page 77.

The --build command repackages the archives in the bar subdirectory into the application package of the pkg subdirectory. The following table lists the types of archives that may reside in the bar subdirectory.

**Table 48 Valid Binary Archive Types** 

File Extension	Archive Type
.cpio	Unix CPIO Archive
.msi	Microsoft Installer
.rpm	RPM Package Manager
.tar	Tape Archive
.tar.bz2	bzip2 compressed Tape Archive
.tar.gz	gzip compressed Tape Archive
.zip	Info-Zip compatible Zip

# Specifying Passthru Packages

Unlike an archive in the bar subdirectory, a passthru package is not extracted and repackaged. The --addPassthruPkg command copies a passthru package unchanged into the pkg subdirectory. The package specified by --addPassthruPkg cannot reside in the ISM directory. The following example adds a passthru package to an ISM and designates the package for addition to the software policy:

```
ismtool --addPassthruPkg /tmp/bos.rte.libs.5.1.0.50.U --pkgType lpp ISMNAME ismtool --attachPkg bos.rte.libs-5.1.0.50 --attachValue true ISMNAME
```

## Compiling Source (Unix Only)

The --build command recursively searches the src subdirectory for speciles (files ending in .spec)). If found, a specile is compiled into Bourne Shell and executed. Speciles are written in a simplified derivative of the RPM specile language. The ISMTool's specile-like language compiler allows you to use existing RPM speciles with minimal modifications.

For more information about the specfile language, see the Maximum RPM document, located at the following URL:

```
http://www.rpm.org/max-rpm/index.html
```

## **Example Specfile**

Here is an example of a simple ISM specfile for NTP 4.1.2:

IDK Build Environment 77

```
Name: %{ismname}
Version: %{version}
# prep, build, install, files
Source: http://www.eecis.udel.edu/~ntp/ntp spool/ntp4/ntp-4.1.2.tar.gz
%prep
%setup -n ntp-4.1.2
%build
%ifos Solaris2.7
echo ''do something Solaris2.7 specific''
%endif
%ifos Linux
echo ''do something Linux specific''
%endif
./configure --prefix=%prefix
make
%install
/bin/rm -rf $ISM BUILD ROOT
make install prefix=$ISM BUILD ROOT/%{prefix}
%files
%defattr(-,root,root)
%prefix
```

### Specfile Preamble

The preamble specifies information to be fetched from the ISM with the program ismget. The following lines fetch the name, version, and prefix of the ISM.

```
%define ismname %(../ism/bin/ismget name)
%define version %(../ism/bin/ismget version)
%define prefix %(../ism/bin/ismget prefix)
```

This fetched information can be useful in the set up and compilation of sources. However, the %define commands are optional. The only required tags in the preamble are Name and Version.

### %prep

The %prep section is designed to prepare sources for compilation. This involves uncompressing and untaring source distributions. A single source file is identified with the Source tag. A list of sources are identified by a vector of tags: Source0, Source1, . . . . Similarly, patches are identified by either a Patch tag or a vector of tags: Patch0, Patch1, . . . . The ISMTool duplicates the macro functionality as documented in Maximum RPM. The %setup macro controls how sources are unpacked. The %prep section can also manage patching using the %patch macro.

### %build

The shell script commands in the %build section will transform the sources into binaries. Compiling from source usually involves running ./configure -prefix=%{prefix} and make. It is possible to perform configuration switching based on the platform (operating system). The platform tags are designed for backward compatibility to RPMs found in real-world installations. The following platform strings are some examples that can be used in ISMTool specifles for platform branching:

```
Linux
RedHat
RedHat-Linux-7.2
RedHat-Linux-AS2.1
Solaris
Solaris2.8
Solaris-2.8
SunOS
SunOS5.7
SunOS-5.7
hpux
hpux11.00
hpux-11.00
HPUX
HPUX11.00
HPUX-11.00
aix
aix4.3
aix-4.3
AIX
AIX4.3
AIX-4.3
```

### %install

The %install section specifies the copying of files from the build to a virtual install location. For example, if the %prefix is set to /usr/local, the following line would install NTP into / usr/local/bin:

```
make install prefix=$ISM BUILD ROOT/%{prefix}
```

The variable \$ISM\_BUILD\_ROOT (or equivalently \$RPM\_BUILD\_ROOT) is the location of a temporary directory inside the ISM's tmp directory. This temporary directory will serve as the virtual install root where the directives in the %files section will be applied.

The %install section also indicates where the files from a binary install could be extracted. In a binary install, the files resulting from a binary install on a development server can be packaged into the virtual install location. However, if that is not possible then a binary installer could be transported to the end system and installed with an ISM post-install hook. In this case, you would create a binary archive of the installer and copy it to the ISM's bar subdirectory.

### %files

In the specfile, the output of the source transformation phase is a set of files indicated by the directives in the %files section. These files are archived into a cpio in the ISM's bar subdirectory.

IDK Build Environment 79

The final phase of the source transformation is to select the files installed into the \$ISM\_BUILD\_ROOT. The directives in the %files section are a subset of the selection mechanisms documented in Maximum RPM. These directives specify a list of files or directories (which are recursively gathered) relative to \$ISM\_BUILD\_ROOT. In this example, the install is into the path \$ISM\_BUILD\_ROOT/%{prefix}. To select these files for packaging, you would simply give the %prefix as the directory to package.

In addition to selecting files by naming files or directories, meta information can be described. The line %defattr(-,root,root) tells the archive engine to use the modes it finds in the file system, but to create the archive replacing the file ownerships it finds in the file system with root, root. For full documentation of %defattr() and %attr(), see Maximum RPM.

# ISM Name, Version Number, and Release Number

This section includes the following:

- Initial Values for the ISM Name, Version, and Release
- ISM Version and Release Numbers Compared
- Upgrading the ISM Version

## Initial Values for the ISM Name, Version, and Release

The --new command creates a directory for the new ISM and specifies the internal base name of the ISM. For example, the following command creates the mystuff directory in the file system, sets the internal base name to mystuff, and sets the version number to 1.0.0.

```
ismtool --new mystuff
```

In most cases, you specify the version number with --new. The following command creates a directory named ntp-1.4.2, sets the internal base name to ntp, and sets the version number to 1.4.2:

```
ismtool --new ntp-1.4.2
```

To view the internal base name, version number, and release numbers, use the --info command:

```
ismtool --info ntp-1.4.2.
```

The output generated by the preceding command includes the following:

```
name: ntp
version: 4.2.1
appRelease: 0
ctlRelease: 0
```

# ISM Version and Release Numbers Compared

ISM version and release numbers differ in several ways. You may specify the version number with either the --new or --version commands. The ISMTool automatically generates the release numbers; you cannot specify them. The version number applies to the entire ISM. The

application and control packages each have separate release numbers. The --build command increments the release numbers whenever it re-generates the packages. Because application and control packages can be built independently, the packages may have different release numbers.

The names of the application and control packages include the internal base name, version number, and release number. For example, the ntp-4.1.2-3.i386.rpm application package has a version number of 4.1.2 and a release number of 3. See also Packages Created by the -build Command on page 76.

To display the version of the IDK (not the ISM), enter the following:

```
ismtool --myversion
```

## Upgrading the ISM Version

Although you may modify the internal base name (with --name) and the version number (with --version), this practice is not recommended because it does not automatically change the directory name. If you change the internal base name or version, to avoid confusion you should also rename the directory containing the ISM.

The recommended practice is to use a matching internal base name, version number, directory name, and software policy path. For example, to upgrade foo-1.2.7 to foo-1.2.8, you would follow these steps:

1 At the same directory level as foo-1.2.7, create a new ISM directory:

```
ismtool --new foo-1.2.8
```

- 2 Copy archives to the foo-1.2.8/bar directory or specify passthru packages.
- 3 Set the path to the software policy at the same level as the previous version.

### Unix:

```
ismtool --opswpath 'MyFolder/{$NAME}/{$VERSION}'
Windows:
ismtool --opswpath "MyFolder/{$NAME}/{$VERSION}"
```

The --opswpath command replaces the NAME variable with foo and the VERSION variable with 1.2.8. To see the current values of the variables, use the --info command. For more information on variable substitution, see ISMTool Variables on page 108.

- 4 Build and upload the foo-1.2.8 ISM with the ISMTool.
- 5 In the SA Client, detach the foo-1.2.7 policy from the managed servers.
- 6 (Optional) Remove the foo-1.2.7 policy.
- 7 Remediate managed servers against the new software policy.

IDK Build Environment 81

# 6 IDK Scripts

# Overview of ISM Scripts

ISM scripts are Unix shell or Windows command-line scripts that reside in the ISM directory. The sections that follow describe the different type of ISM scripts:

- Installation Hooks: Bundled into the ISM's control package by the ISMTool --build command, the installation hooks are run by the native packaging engine (such as rpm) on the managed server. Installation hooks may invoke control scripts.
- **Control Hooks**: Also bundled into the ISM's control package, the control scripts perform day-to-day, application-specific tasks such as starting software servers.
- **Installation Scripts**: Not contained in the control package, but instead stored in the Software Repository, installation scripts can be viewed on the Properties of a package in the SA Client.

The overall process for developing and running installation hooks and control scripts follows:

- 1 invoke the ISMTool --new command, which creates the default installation hooks.
- 2 With a text editor, create the control scripts.
- 3 With a text editor, modify the default installation hooks, which may call control scripts.
- 4 With the ISMTool, build and upload the ISM.
- 5 In the SA Client, install the application contained in the ISM onto a managed server. During the installation, the pre-installation and post-installation hooks are run on the managed server.
- 6 During the production lifetime of the application, run or schedule the control scripts.
- 7 At the end of the application's life cycle, with the SA Client, uninstall the application. During the uninstallation, the pre-uninstallation and post-uninstallation hooks are executed on the managed server.

Installation scripts have a different overal process than installation hooks and control scripts. For more information, see Installation Scripts on page 94.

An ISM script cannot call program (such as rpm or pkgadd) that locks the package associated with the script.

## Installation Hooks

The installation hooks are scripts that reside in the <code>ism/pkg</code> subdirectory. (Some documents refer to the installation hooks as "packaging scripts.") The installation hooks are run at certain stages during the installation and uninstallation of applications on managed servers.

## Creating Installation Hooks

The ISMTool --new command creates the following installation hooks:

#### Unix:

```
ism/pkg/
    ism_check_install
    ism_post_install
    ism_post_uninstall
    ism_pre_install
    ism_pre_uninstall

Windows:

ism\pkg\
    ism_post_install.cmd
    ism_post_uninstall.cmd
    ism_pre_install.cmd
    ism_pre_install.cmd
    ism_pre_install.cmd
```

To customize the installation hooks, you modify them with a text editor. Although you may edit the installation hooks, you cannot change their file names.

The default ism\_pre\_install and ism\_post\_uninstall hooks are just stubs; they perform no actions. The default ism\_post\_install hook calls the ism\_configure and ism\_start control scripts. The default ism\_pre\_uninstall hook calls the ism\_stop control script. Note that the control scripts are not created automatically by the ISMTool; you must create them with a text editor. (See Control Scripts on page 88.)

For the contents of the default installation hooks created by the --build command, see the following sections:

- Default Installation Hooks for Unix on page 86
- Default Installation Hooks for Windows on page 87

### Check Installation Hook

Some native packaging engines support the <code>ism\_check\_install</code> hook directly; others do so implicitly with the <code>ism\_pre\_install</code> hook. The ISMTool maps the <code>check\_install</code> feature onto the native packaging engine. If the <code>check\_install</code> script returns a non-zero code, the install is halted.

### Invocation of Installation Hooks

When you install (or uninstall) the application of an ISM onto a managed server, the native packaging engine on the server invokes the installation hooks. (You do not run the installation hooks directly.) For example, on a Linux system, the <code>rpm</code> utility invokes <code>ism\_pre\_install</code> immediately before it installs the application bits and invokes <code>ism\_post\_uninstall</code> right after it removes the bits.

See also Invocation of Installation Scripts and Hooks on page 95.

## Installation Hooks and ZIP Packages

Unlike some other packaging engines, the ZIP packaging engine used by HP Server Automation does not support installation hooks. If the ZIP packaging engine is specified and the installation hook files are not empty, the ISMTool generates a warning and ignores the installation hook files.

## **ZIP Packages and Installation Directories**

The ZIP packages created by the IDK are not relocatable. In other words, the same ZIP package cannot be used to install multiple instances of an application in different directories on a single managed server. Therefore, if the end user changes the ZIP package's Install Path field in the SA Client, the package installation will fail. To change the installation directory, the ISM developer specifies a new path with the <code>--prefix</code> or <code>--ctlprefix</code> option, builds a new ISM, and uploads the new ISM to the core. (For Windows NT4, these options are required and cannot specify variables.)

As a best practice for ZIP packages, the ISM developer should include a warning in the ISM's description similar to the following: "WARNING: Do not change the Install Path of this package."

### Installation Hook Functions

You can customize the installation hooks to perform actions such as those listed in the following table.

**Table 49 Installation Hook Functions** 

Install hook	common functions
ism_pre_install	create required directories, create users, set directory permissions
ism_post_install	<pre>call ism_configure control script, call ism_start control script (to start a web server, for example)</pre>
ism_pre_uninstall	call ism_stop control script (to stop a server)
ism_post_uninstall	do any required clean up

# Scripts for Control-Only ISMs

If you specify the <code>--skipApplicationPkg</code> option, the ISMTool will not build the application package, enabling the creation of a control-only ISM. You can use this feature to build a controller for an application that is not installed or packaged with the ISMTool. Examples are controllers for core operating system functions, currently running applications that cannot be packaged, and specialized hardware.

During the installation and uninstallation of a control-only ISM, the <code>ism\_ctl\_post\_install</code> and <code>ism\_ctl\_pre\_uninstall</code> scripts are run. (The scripts are run for all ISMs, but typically you specify them only for control-only ISMs.) Because these scripts are not generated by the ISMTool, you must create them before running the <code>--build</code> command. The following listing shows the required names and locations of these scripts:

IDK Scripts 85

### Unix:

## Location of Installation Hooks on Managed Servers

On your development system, the --build command bundles the installation hooks into the ISM's control package. On the managed server, the contents of the control package are installed into the directory indicated by the ctlprefix of the ISM. By default, the installation hooks are installed into the following directory:

#### Unix:

```
/var/opt/OPSWism/<ism-name>/pkg
```

### Windows:

```
%ProgramFiles%\OPSWism\<ism-name>\pkg
```

To change the default directory of the installation hooks, specify the --ctlprefix option before building and uploading the ISM. If you specify the ctlprefix as follows, for example, the installation hooks will be installed in /usr/local/ntp-4.1.2/pkg:

```
ismtool --ctlprefix /usr/local ntp-4.1.2
```

### Default Installation Hooks for Unix

The default ism pre install hook:

```
#!/bin/sh
#
# ISM Pre Install Script
#
. 'dirname $0'/../env/ism.sh
```

The default ism post install hook:

```
#!/bin/sh
#
# ISM Post Install Script
#
. 'dirname $0'/../env/ism.sh
if [ -x ${ISMDIR}/control/ism_configure ]; then
${ISMDIR}/control/ism_configure
fi
if [ -x ${ISMDIR}/control/ism_start ]; then
${ISMDIR}/control/ism_start
fi
```

```
The default ism\_pre\_uninstall hook:
```

```
#!/bin/sh
#
# ISM Pre Uninstall Script
#
. 'dirname $0'/../env/ism.sh
if [ -x ${ISMDIR}/control/ism_stop ]; then
${ISMDIR}/control/ism_stop
fi
```

### The default ism post unininstall hook:

```
#!/bin/sh
#
# ISM Post Uninstall Script
#
. 'dirname $0'/../env/ism.sh
```

### Default Installation Hooks for Windows

### The default ism pre install.cmd hook:

```
@echo off
REM
REM ISM Pre Install Hook
REM
SETLOCAL
REM
REM %1 specifies the full path to the ISM.CMD file
REM Call ISM.CMD to define ISM environment variables
REM
call %1
ENDLOCAL
```

### The default ism post install.cmd hook:

```
@echo off
REM
REM ISM Post Install Script
REM
SETLOCAL
REM
REM %1 specifies the full path to the ISM.CMD file
REM Call ISM.CMD to define ISM environment variables
REM
call %1
REM
REM Call the ISM's configure script
IF EXIST "%ISMDIR%\control\ism configure.cmd"
call "%ISMDIR%\control\ism configure.cmd"
REM
REM Call the ISM's start script
REM
```

IDK Scripts 87

```
IF EXIST "%ISMDIR%\control\ism start.cmd"
   call "%ISMDIR%\control\ism start.cmd"
   ENDLOCAL
The default ism pre uninstall.cmd hook:
   @echo off
   REM
   REM ISM Pre Uninstall Hook
   REM
   SETLOCAL
   REM
   REM %1 specifies the full path to the ISM.CMD file
   REM Call ISM.CMD to define ISM environment variables
   REM
   call %1
   REM
   REM Call the ISM's stop script
   IF EXIST "%ISMDIR%\control\ism stop.cmd"
   call "%ISMDIR%\control\ism stop.cmd"
   ENDLOCAL
The default ism post unininstall.cmd hook:
   @echo off
   REM
   REM ISM Post Uninstall Script
   REM
   SETLOCAL
   REM
   REM %1 specifies the full path to the ISM.CMD file
   REM Call ISM.CMD to define ISM environment variables
   REM
   call %1
```

# **Control Scripts**

The ISM control scripts reside in the ism/control directory. Control scripts perform housekeeping or maintenance tasks for an application after it has been installed.

Installation hooks can run control scripts. If a task is performed during an installation (or uninstallation) but might also be performed on a regular basis, it should be coded as a control script. For example, the <code>ism\_post\_install</code> hook can invoke the <code>ism\_start</code> control script to start an application immediately after installation. Also, the <code>ism\_pre\_uninstall</code> hook can invoke the <code>ism\_stop</code> control script to shutdown the application.

Users can run control scripts from the ISM Control window of the SA Client. Advanced users can run control scripts from the command line in the Global Shell.

### **Creating Control Scripts**

Unlike installation hooks, control scripts are not created by the ISMTool; you create control scripts with a text editor. You may add any number of control scripts to the <code>ism/control</code> subdirectory. By convention, the file names for control scripts are as follows:

### Unix:

```
ism/control/
    ism_start
    ism_stop
    ism_configure
    ism reconfigure
```

### Windows:

```
ism\control\
    ism_start.cmd
    ism_stop.cmd
    ism_configure.cmd
    ism_reconfigure.cmd
```

The control script name might appear differently in the ISM Control window of the SA Client. The Action field of the ISM Control window displays the name of the control script, but without the leading <code>ism\_</code> or the file type extension. For example, a control script named <code>ism\_start.cmd</code> appears in Action field as <code>start</code>. The Action field displays only the first 25 characters of a control script name. Therefore, the first 25 characters of the names should be unique. For both Unix and Windows, the leading <code>ism\_</code> must be lower case; otherwise, the Action field displays the prefix.

For Unix, make sure that the control scripts under ism/control are executable. Otherwise, they will not appear in the SA Client.

## **Control Script Functions**

Control scripts are for repetitive tasks needed to manage an application. The following table summarizes typical uses for control scripts.

**Table 50 Control Script Functions** 

Control Script	common functions
ism_start	notifies any companion or dependent servers, starts the application
ism_stop	notifies any companion or dependent servers, stops the application
ism_configure	performs configuration operations
ism_reconfigure	<pre>similar to ism_configure, but calls ism_stop first and ism_start afterwards</pre>

IDK Scripts 89

### Location of Control Scripts on Managed Servers

Like installation hooks, control scripts are bundled into the control package by the --build command. On the managed server, control scripts reside in the directory indicated by the ISM ctlprefix value. By default, control scripts are installed in the following directory on a managed server:

### Unix:

/var/opt/OPSWism/<ism-name>/control

### Windows (except for NT4):

%ProgramFiles%\OPSWism\<ism-name>\control

To change the default directory, specify the --ctlprefix option with ISMTool. For Windows NT4, --ctlprefix must be specified and cannot contain variables.

# Dynamic Configuration with ISM Parameters

The ISM parameter utility enables control scripts and installation hooks to access the values of SA custom attributes. The key of an ISM parameter matches the name of its corresponding custom attribute. The value of a custom attribute determines the value of the parameter. The source of a custom attribute is an SA object such as a facility, customer, server, or device group.

Set with the SA Client, a custom attribute is a name-value pair that holds configuration information. For example, to designate the port number of an Apache web server, a custom attribute named APACHE\_1.3\_PORT could have a value of 80. If an ISM has a parameter named APACHE\_1.3\_PORT, a control script could access the current value of the custom attribute.

Using the ISM Control window of the SA Client, an end-user can view the source (SA object) of a parameter, view the parameter value, and override the parameter value.

# **Development Process for ISM Parameters**

The overall process for developing and using ISM parameters follows:

- 1 With the ISMTool, add a new parameter.
- 2 With a text editor, write a control script (or modify an installation hook) to access the parameter.
- 3 With the ISMTool, build and upload the ISM.
- 4 In the SA Client, install the application contained in the ISM onto a managed server.
- 5 In the SA Client, create a custom attribute with the same name as the parameter.
- In the SA Client, run the control script on the managed server. At runtime, the script retrieves the parameter (control attribute) value from HP Server Automation.

### Adding, Viewing, and Removing ISM Parameters

The ISMTool --addParam command creates a new parameter, which may be fetched by any script in the ISM. A parameter is a tuple with four fields, each specified by an ISMTool option. The following table lists the fields and their corresponding options.

Table 51 ISM Parameter Fields

Parameter field	ISMTool option	Description
Name	addParam	The name of the ISM parameter, which must match the name of the custom attribute.
Default Value	paramValue	The default value of the parameter. The script uses the default value if a matching custom attribute is not found.
Туре	paramType	The data type of the parameter. Allowed values: 'String' 'Template'
Description	paramDesc	Text describing the parameter.

The following Unix command adds a parameter named NTP\_SERVER to the ntp-4.2.1 ISM:

```
ismtool --addParam NTP_SERVER \
    --paramValue 127.0.0.1 \
    --paramType 'String' \
    --paramDesc 'NTP server, default to loopback' ntp-4.2.1
```

To view the parameters that have been added to the ntp-4.2.1 ISM, enter the following:

```
ismtool --showParams ntp-4.2.1
```

To remove the parameter added in this example, you enter the following command:

```
ismtool --removeParam NTP SERVER ntp-4.2.1
```

## Accessing Parameters in Scripts

After you've added a parameter with ISMTool, you can write an ISM control script to access the parameters. The supported scripting languages follow:

- Bourne Shell
- Korn Shell
- Windows command shell
- Python
- Perl

Shell scripts access the parameters through environment variables, Python scripts through dictionaries, and Perl scripts through hash tables.

IDK Scripts 91

### The ISM parameters Utility

To fetch parameters, a control script runs the parameters utility, which resides in the ISM shared runtime package. Only those parameters defined with the --addParam command can be fetched.

The parameters utility has the following syntax:

```
parameters [options]
--scope <scope> ; server|servergroup|customer|facility|
               ; servicelevel|os|custapps|webserver|appserver|
               ; dbserver|systemutilities|osextras|install|
               ; default (default is all)
-s/--sh
                      ; Bourne Shell syntax
-k/--ksh
                      ; Korn-Shell syntax
-p/--python
                      ; Python repr'ed dictionary
-1/--perl
                      ; PERL map
                      ; Windows Cmd syntax
-c/--cmd
-c/--cma
-b/--vbscript
                      ; Windows VBScript syntax
-h/--help
                      ; Help
-v/--version
                      ; Version
```

The --scope option limits the search for the custom attribute to the specified area of HP Server Automation. For example, if you specify --scope facility and a custom attribute has been defined for both the facility and the customer, then the custom attribute of the customer is not considered. See also: Search Order for Custom Attributes on page 93.

If the parameters utility encounters an error during retrieval, it returns a special parameter named OPSW ISMERR, which contains a brief description of the error encountered.

## **Example Scripts**

The following Bourne Shell example is a control script that configures the NTP time service on Unix. The parameters utility retrieves two parameters, NTP\_CONF\_TEMPLATE and NTP\_SERVER, that have been defined for the ISM.

```
#!/bin/sh
. 'dirname $0'/../env/ism.sh
eval '${ISMDIR}/bin/parameters'
echo $NTP_CONF_TEMPLATE | \
sed "s/NTP SERVER TAG/$NTP SERVER/" > /etc/ntp.conf
```

The following control script, written in Python, also configures NTP.

```
#!/usr/bin/env python
import os
import sys
import string
ismdir=os.path.split(sys.argv[0])[0]
cmd = '%s --python' % (os.path.join(ismdir,'bin','parameters'))
params = eval(os.popen(cmd,'r').read())
template = params['NTP_CONF_TEMPLATE']
value = params['NTP_SERVER']
conf = string.replace(template,'NTP_SERVER_TAG',value)
fd=open('/etc/ntp.conf','w')
fd.write(conf)
fd.close()
```

The following example shows a configuration control script for Windows. In this example, for 32 bit Windows operating systems, each parameter is output in the form of name=value (one per line).

The Windows FOR command sets each parameter as an environment variable. (In the listing that follows, the FOR command is split into two lines, but in the actual script, the FOR command must be on a single line.) Finally, the parameters are passed to an NTP configuration script named WindowsNTPConfigureScript.cmd.

```
@echo off
SETLOCAL
cd /d %ISMDIR%
for /f "delims== tokens=1,2" %%i in ('""bin\parameters.cmd""') do set
%%i=%%j WindowsNTPConfigureScript.cmd %NTP_CONF_TEMPLATE% %NTP_SERVER%
ENDLOCAL
```

### Search Order for Custom Attributes

With the SA Client, you can set a custom attribute in several places. For example, you could set a custom attribute named APACHE\_1.3\_PORT to 8085 for a managed server named foo.hp.com, and you could set the same custom attribute to 80 for the Widget Corp. customer, which is associated with the foo.hp.com server. At runtime, if a control script on foo.hp.com accesses the APACHE\_1.3\_PORT parameter, which value will it fetch? In this case, the value will be 8085 because a custom attribute for a server occurs first in the search order.

Note that if a custom attribute is not found, the script uses the default parameter value that you set with the ISMTool --paramValue option.

### Default Search Order

The default search order for custom attributes is as follows:

- 1 Server
- 2 Device Group
- 3 Customer
- 4 Realm
- 5 Facility
- 6 Operating system.
- 7 ISM (created in the software policy during the upload operation)
- 8 Patch Policy
- 9 Software Policy

Multiple device groups and service levels are searched alphabetically. For example, if a server belongs to the ABC and XYZ groups, the ABC group is searched for the custom attribute before the XYZ group. A server group that is a subgroup does not inherit the custom attributes of its parent group.

IDK Scripts 93

# Installation Scripts

The installation scripts reside in the pad subdirectory. Like installation hooks, the installation scripts are run at specific stages during the installation and uninstallation of an application on a managed server.

## Differences Between Installation Scripts and Hooks

Although they serve a similar purpose, installation scripts and hooks have several differences, as noted in the following table.

Table 52 Differences Between Installation Scripts and Hooks

installation scripts	installation hooks
Displayed by the Properties of the package in the SA Client.	Displayed by the Contents of the package in the SA Client. (Only RPMs are displayed.)
Reside in the pad subdirectory.	Reside in the ism/pkg subdirectory.
Stored in Model Repository (after an upload).	Bundled in the control package, installed on the managed server in the directory specified by ctlprefix.
Run by the Server Agent.	Run by the native packaging engine.
Can be defined for each package in the ISM.	Defined for the entire ISM.

# Creating Installation Scripts

Although the ISMTool creates the pad subdirectory structure, it does not create default installation scripts. For each package created with --build or added with --addPassthruPkq, the ISMTool creates a subdirectory as follows:

```
pad/<package-name>/scripts
```

For example, on Linux the --build command would create the following subdirectories for an ISM named ntp-1.4.2:

```
pad/ismruntime-rpm-2.0.0-1.i386.rpm/scripts
pad/ntp-ism-4.2.1-1.i386.rpm/scripts
pad/ntp-4.2.1-1.i386.rpm/scripts
```

With a text editor, you create the installation scripts in the scripts subdirectory. For example, you could create installation scripts for the ntp-4.2.1-1.i386.rpm package as follows:

The file names of the installation scripts must match the preceding example. For example, the script invoked immediately after the installation must be named postinstallscript.

### Invocation of Installation Scripts and Hooks

If an ISM has both installation scripts and hooks, when an application is installed on a managed server, HP Server Automation performs tasks in the following order:

- 1 Installs the ISM runtime package.
- 2 Installs the ISM control package.
- 3 Runs preinstallscript (installation script).
- 4 Runs ism pre install (installation hook).
- 5 Installs the application package (the application bits).
- 6 Runs ism post install (installation hook).
- 7 Runs ism configure (control script).
- 8 Runs ism\_start (control script).
- 9 Runs postinstallscript (installation script).

During the uninstallation of an application on a managed server, HP Server Automation performs actions in the following order:

- 1 Runs preuninstallscript (uninstallation script).
- 2 Runs ism\_pre\_uninstall (uninstallation hook).
- 3 Runs ism stop (control script).
- 4 Uninstall the application package (the application bits).
- 5 Runs ism post uninstall (uninstallation hook).
- 6 Runs postuninstallscript (uninstallation script).
- 7 Uninstalls the ISM control package.
- 8 Uninstalls the ISM runtime package.

IDK Scripts 95

# 7 IDK Commands

# **ISMTool Argument Types**

Table 53 defines the argument types that are used in the ISMTool commands defined in the rest of this chapter. The ISMNAME argument type, for example, is specified by the syntax of the ISMTool --new command.

**Table 53 ISMTool Argument Types** 

Argument Type	Description	Example
PATH	Absolute file system path.	/foo/bar
STRING	Text string with no spaces.	foobar
TEXT	Arbitrary quoted text. On Unix you enclose the text in single quotes; on Windows use double quotes.	'This is some text'
BOOL	Boolean.	true <b>or</b> false
ISMFILE	Path to a valid .ism file in the file system. This file would unpack into an ISMDIR.	/foo/bar/name.ism
ISMDIR	Path to a valid extracted ISMFILE or to a newly created ISM.	xyz /home/sam/xyz
ISMNAME	Name for a newly-created ISM. The ISMNAME can have the format STRING or STRING-VERSION.	ntp ntp-4.1.2
VERSION	A STRING that represents the version of the ISM. The VERSION cannot contain spaces and must be a legal version string for the native packaging engine.	1.2.3 4.13 0.9.7b
HOST[:PORT]	Host and optional port.	www.foo.com www.foo.com:8000 192.168.1.2:8000
BYTES	Integer number of bytes.	42
SECONDS	Integer number of seconds.	300
PARAMTYPE	Expected type of the parameter data. The only allowed values are the constants 'String' and 'Template'. On Unix you enclose the values in single quotes; on Windows use double quotes.	'String' 'Template'

## ISMTool Informational Commands

This section describes the ISMTool commands that provide information about the build environment.

### --help

Display the ISMTool command-line help.

### --env

Display the locations of system-level tools found in the environment. This command is helpful for investigating build problem and for verifying that the environment variable ISMTOOLBINPATH is set correctly. For example, on a Unix system --env might display the following:

```
% ismtool --env
bzip2: /usr/local/ismtool/lib/tools/bin/bzip2
cpio: /usr/local/ismtool/lib/tools/bin/cpio
gzip: /usr/local/ismtool/lib/tools/bin/gzip
install: /usr/local/ismtool/lib/tools/bin/install
patch: /usr/local/ismtool/lib/tools/bin/patch
python: /usr/local/ismtool/lib/tools/bin/python
pythonlib: /usr/local/ismtool/lib/tools/lib/python1.5
rpm2cpio: /usr/bin/rpm2cpio
rpm: /bin/rpm
rpmbuild: /usr/bin/rpmbuild
tar: /usr/local/ismtool/lib/tools/bin/tar
unzip: /usr/local/ismtool/lib/tools/bin/unzip
wget: /usr/local/ismtool/lib/tools/bin/wget
zip: /usr/local/ismtool/lib/tools/bin/zip
zipinfo: /usr/local/ismtool/lib/tools/bin/zipinfo
pkgengines: ['rpm4']
```

### --myversion

Display the version of the ISMTool.

### --info ISMDIR

Display an overview of the internal information about the ISM contained in the directory ISMDIR. After the build is completed, more detailed information is available, which can be viewed in browser at this URL:

```
<ISMDIR>/doc/index/index.html
```

### --showParams ISMDIR

Display the name, default value, type, and description for each control parameter.

## --showPkgs ISMNAME

Display the list of all packages managed by the ISM. This list includes the control package, the application package, all passthru packages, and all inner packages contained in passthru packages. Examples of inner packages are Solaris package instances contained in Solaris packages, or an update fileset contained in a AIX LPP package. For each managed package, the package name, type, attached status and all meta data that can be set will be listed.

### --showOrder ISMNAME

Display the current install order of attached packages managed by the ISM.

## --showPathProps ISMNAME

This option is deprecated in HP Server Automation 6.0.

Displays the values currently specified for software policy meta data.

# ISMTool Creation Commands

This section describes the ISMTool commands that generate the ISM directory structure.

### --new ISMNAME

Create a new ISM, which consists of directory that contains subdirectories and files. The value of ISMNAME specifies the name of the newly-created ISM directory. The internal ISM name varies with the format of ISNAME.

For example, the following command creates an ISM directory called foobar. The internal name of the ISM is foobar and the initial version of the ISM defaults to 1.0.0.

```
% ismtool --new foobar
```

The next command creates an ISM directory called ntp-4.1.2. The internal name of the ISM is ntp and the initial version of the ISM is 4.1.2. Note that the internal name of the ISM does not include -VERSION.

```
% ismtool --new ntp-4.1.2
```

The name of the ISM directory is independent of the internal ISM name. For example, if the developer renames the ntp-4.1.2 directory to myntp, the internal name of the ISM is still ntp and the version of the ISM remains 4.1.2.

## --pack ISMDIR

Creates a ZIP archive of the ISM contained in ISMDIR. The name of the archive will be <ismname-version>.ism. Note that the contents of ISMDIR must be less than 2GB. (If the size is greater than 2 GB, then use the zip or tar utility instead.) An example of --pack follows:

Unix:

IDK Commands 99

```
% ismtool --new tick
   % ismtool --version 3.14 tick
   % ls
   tick/
   % mv tick spooon
   % ls
   spooon/
   % ismtool --pack spooon
   spooon/ tick-3.14.ism
Windows:
   % ismtool --new tick
   % ismtool --version 3.14 tick
   11/21/2003 10:17a <DIR> tick
   % move tick spoon
   % dir
   11/21/2003 10:17a <DIR> spoon
   % ismtool --pack spoon
   % dir
   11/21/2003 10:17a <DIR> spoon
   11/21/2003 10:17a 1,927,339 tick-3.14.ism
```

## --unpack ISMFILE

Unpacks the ISM contained in the ZIP file named ISMFILE. The ISM is unpacked into the ISMDIR that was specified when the ISMFILE was created with the --pack command. The following example uses the ISMFILE created in the --pack example:

Unix:

```
% ls
spooon/ tick-3.14.ism
% rm -rf spooon
% ls
tick-3.14.ism
% ismtool --unpack tick-3.14.ism
% ls
spooon/ tick-3.14.ism
```

### Windows:

```
% dir
11/21/2003 10:17a <DIR> spoon
11/21/2003 10:17a 1,927,339 tick-3.14.ism
% rmdir /s /q spoon
% dir
11/21/2003 10:17a 1,927,339 tick-3.14.ism
% ismtool --unpack tick-3.14.ism
% dir
11/21/2003 10:17a <DIR> spoon
11/21/2003 10:17a 1,927,339 tick-3.14.ism
```

## ISMTool Build Commands

This section describes the ISMTool commands that build and modify an ISM.

### --verbose

Display extra debugging information.

### --banner

Suppress the display of the output banner.

### --clean

Clean up all files generated as a result of a build. This removes temporary files and all build products.

### --build

Builds the ISM, creating the packages in the pkg subdirectory.

The primary purpose of the build command is to create the packages contained in the ISM. Optionally, the build command may invoke source compilation and run pre-build and post-build scripts.

## --upgrade

Upgrade the ISM to match the currently installed version of the ISMTool.

New releases of the ISMTool may fix defects or modify how it operates on an extracted ISMDIR. If the version of the currently installed ISMTool is different from the version of the ISMTool that created the ISM, the developer may need to perform certain actions. Note that minor and major downgrades are not allowed. For example, if version 2.0.0 of the ISMTool created the ISM, then version 1.0.0 of the ISMTool cannot process the ISM. Table 54 lists the developer actions if the currently installed and previous versions of ISMTool are not the same.

IDK Commands 101

Table 54 ISMTool Upgrade Actions

ISMTool Version Currently Installed	ISMTool Version Used to Create the ISM	Developer Action
1.0.1	1.0.0	PATCH increment. Developer action is not needed. This is considered a simple automatic upgrade which is forward AND backward compatible.
1.0.0	1.0.1	PATCH decrement. Automatic downgrade. No action needed.
1.1.0	1.0.0	MINOR increment. The developer must apply the upgrade command to the ISM. There may be small operational differences or enhanced capability. Warning: This operation is not reversible. Minor upgrades are designed to be as transparent as possible.
2.0.0	1.0.0	MAJOR increment. The developer must apply the upgrade command to the ISM. There may be large operational differences. The developer will probably need to perform other actions specified in release notes.
1.0.0	2.0.0 or 1.1.0	MAJOR or MINOR decrement. This downgrade path is not allowed. The ISM cannot be processed with the installed version of the ISMTool.

### --name STRING

Change the internal name of the ISM to STRING. The ISMDIR, the top level directory of an extracted ISM, can have a different name than the internal name of the ISM. To change both names, use the ISMTool —name command to change the internal name and a file system command to change the directory name. If the STRING format is not valid for the native packaging engine, the problem will not be found until a —build is issued and the packaging engine throws an error.

### --version STRING

Change the internal version field of the ISM. The STRING cannot contain spaces. The -version command performs no other checks on the STRING format. If the STRING format is
not valid for the native packaging engine, the problem will not be found until a --build is
issued and the packaging engine throws an error.

# --prefix PATH

Change the install prefix of an ISM. The PATH is used by the build-from-source feature of the ISMTool and also by the drivers for the packaging engines. During installation on a managed server, the application files packaged in the ISM are installed in the location relative to the PATH. In the SA Client, the PATH appears in the Install Path field in the package's properties. In the following Unix example, the developer begins with this .tar file:

In this example, a --prefix of '/' would build an application package such that all the files would be installed relative to the file system root.

```
% ismtool --build --prefix '/' --pkgengine rpm4 ntp
% rpm -qlpv ntp/pkg/ntp-1.0.0-1.i386.rpm
drwxr-xr-x 2 ntp ntp 0 Jul 8 16:22 /etc/ntp
-rw-r--r-- 1 root root
                         1808 Nov 22 2002 /etc/ntp.conf
                        7 Jul 8 16:22 /etc/ntp/drift
-rw-r--r-- 1 ntp ntp
                         266 Sep 5 2001 /etc/ntp/keys
-rw----- 1 root root
-rw-r--r-- 1 root root
                          22 Nov 22 2002 /etc/ntp/step-tickers
                       40908 Sep 5 2001 /usr/sbin/ntp-genkeys
-rwxr-xr-x 1 root root
-rwxr-xr-x 1 root root 1019 Sep 5 2001 /usr/sbin/ntp-wait
-rwxr-xr-x 1 root root 252044 Sep 5 2001 /usr/sbin/ntpd
-rwxr-xr-x 1 root root 40460 Sep 5 2001 /usr/sbin/ntpdate
-rwxr-xr-x 1 root root 70284 Sep 5 2001 /usr/sbin/ntpdc
-rwxr-xr-x 1 root root 66892 Sep 5 2001 /usr/sbin/ntpq
-rwxr-xr-x 1 root root 12012 Sep 5 2001 /usr/sbin/ntptime
                         40908 Sep 5 2001 /usr/sbin/ntptimeset
-rwxr-xr-x 1 root root
-rwxr-xr-x 1 root root
                        19244 Sep 5 2001 /usr/sbin/ntptrace
```

It is easy to change the install prefix to '/usr/local':

```
% ismtool --build --prefix '/usr/local' ntp
% rpm -qlpv ntp/pkg/ntp-1.0.0-2.i386.rpm
drwxr-xr-x 2 ntp ntp 0 Jul 8 16:22 /usr/local/etc/ntp
                          1808 Nov 22 2002 /usr/local/etc/ntp.conf
-rw-r--r-- 1 root root
                         7 Jul 8 16:22 /usr/local/etc/ntp/drift
-rw-r--r-- 1 ntp
                  ntp
-rw----
           1 root root
                           266 Sep 5 2001 /usr/local/etc/ntp/keys
-rw-r--r-- 1 root root
                          22 Nov 22 2002 /usr/local/etc/ntp/step-
tickers
          1 root root
                        40908 Sep 5 2001 /usr/local/usr/sbin/ntp-
-rwxr-xr-x
genkeys
-rwxr-xr-x 1 root root
                        1019 Sep 5 2001 /usr/local/usr/sbin/ntp-wait
-rwxr-xr-x 1 root root 252044 Sep 5 2001 /usr/local/usr/sbin/ntpd
-rwxr-xr-x 1 root root 40460 Sep 5 2001 /usr/local/usr/sbin/ntpdate
```

IDK Commands 103

```
5 2001 /usr/local/usr/sbin/ntpdc
                            70284 Sep
-rwxr-xr-x
            1 root
                     root
                                     5 2001 /usr/local/usr/sbin/ntpg
            1 root
                            66892 Sep
-rwxr-xr-x
                    root
                                      5
                                         2001 /usr/local/usr/sbin/ntptime
-rwxr-xr-x
            1 root
                    root
                            12012 Sep
                            40908 Sep
                                     5
                                         2001 /usr/local/usr/sbin/
-rwxr-xr-x
            1 root
                    root.
ntptimeset
-rwxr-xr-x
            1 root root
                           19244 Sep 5 2001 /usr/local/usr/sbin/ntptrace
```

On Windows, there is no standard way to tell an MSI where to install itself. Therefore, application packages built from MSI files found in the bar directory will ignore the --prefix setting. However, for Windows application packages built from ZIP files, the ISMTool will use the --prefix setting. On Windows the prefix must be in this form:

driveletter: \directoryname (for example, D: \mydir). On Windows NT4, --prefix is required and cannot contain variables.

On Unix, the default value of PATH is /usr/local.

## --ctlprefix PATH

Change the install prefix of the control files. Note that this command is not recommended and that you should instead rely on the default values. During installation on a managed server, the control files packaged in the ISM are installed in the location relative to the PATH. In the SA Client, the PATH appears in the Install Path field in the package's properties. On Windows the prefix must be in this form: driveletter:\directoryname (for example, D:\mydir). On Windows NT4, --ctlprefix is required and cannot contain variables.

The default value for PATH follows:

#### Unix:

/var/opt/OPSWism

### Windows:

%ProgramFiles%\OPSWism

On Solaris, if you specify --ctlprefix on Solaris, you will be prompted for the name of the shared run-time package.

## --user STRING (Unix only)

Change the Unix user owner of the files in the application package to STRING. When the files in the package are installed on the managed server, they will be owned by the specified Unix user.

# --group STRING (Unix only)

Change the Unix group owner of the files in the application package STRING.

## --ctluser STRING (Unix only)

Change the Unix user owner of the files in the control package to STRING. The default value is root. When the files in the package are installed on the managed server, they will be owned by the specified Unix user.

## --ctlgroup STRING (Unix only)

Change the Unix group owner of the files in the control package to STRING. The default value is bin.

# --pkgengine STRING (Unix only)

Change the native packaging engine. On systems that have multiple packaging engines available, use this command to switch between them. To view the available engines, issue the --help or --env commands.

Note that if you change the native packaging engine, no packages will be added to the software policy during the --upload operation.

## --ignoreAbsolutePaths BOOL (Unix only)

Ignore the absolute paths in the archive. For example, the following is a binary archive with absolute paths:

```
% tar tvf test/bar/foo.tar
-rw-r--r- root/root 1808 2002-11-22 09:20:36 /foo/bar/baz.conf
```

If the --prefix is set to /usr/local then the install path is ambiguous: Should ISMTool install baz.conf as /foo/bar/baz.conf or /usr/local/foo/bar/baz.conf? If the answer is /foo/bar/baz.conf, then the developer must set the --prefix of the ISM to '/'. However, if the answer is /usr/local/foo/bar/baz.conf, then the developer must specify the --ignoreAbsolutePaths command.

## --addCurrentPlatform (Unix only)

Add the current platform to the ISM's supported list. Note: This command does not make the ISM cross-platform. ISMs can be constructed on different SA-supported platforms. A platform is the combination of OS type and version. Example platforms are: Redhat-Linux-7.2, SunOS-5.9, Windows-2000. To view the currently supported platforms for an ISM use the --info command.

## --removeCurrentPlatform (Unix only)

Removes the current platform from the ISM's supported platform list.

# --addPlatform TEXT (Unix only)

Add to the ISM's supported platform list the platform specified by the TEXT. Because platform support and identification are dynamic, no error checking is done for --addPlatform. For this reason, the recommendation is to use --addCurrentPlatform instead of --addPlatform.

# --removePlatform TEXT (Unix only)

Removes from the ISM's supported platform list the platform specified by the TEXT.

IDK Commands 105

## --target STRING (Unix only)

Warning: This command should only be used by experts.

Allow cross-platform packaging of the application package for the RPM packaging engine. The --target command must be used with --skipControlPkg. The format of the STRING is <arch-os>, for example, i686-linux or sparc-solaris2.7.

## --skipControlPkg BOOL

Prevent the building of the control package. This command allows the ISMTool to support the packaging of files that have no need for a structured application control package.

## --skipApplicationPkg BOOL

Prevent the building of the application package. This command allows the ISMTool to support the creation of a control-only ISM package. This feature can be used to build a controller for an application that is not installed or packaged with the ISMTool. Examples are controllers for core operating system functions, currently running applications that cannot be packaged, and specialized hardware.

## --chunksize BYTES (Unix only)

Limits the number of bytes that will be inserted into an application package. (Heuristics are used to compensate for compression factors.) The binary archive (bar) directory may contain many archives from which to build the application package. If the chunksize is exceeded, then the application archives are grouped into several bins and each bin is turned into a-sub application package. The algorithm is a standard bin-packing heuristic. The movable units are binary archives within the bar directory.

For example, suppose that the output package format is an RPM and has five binary archives: a.tgz (100M), b.tgz(100M), c.tgz (200M), d.tgz (300M), and e.tgz(50M). If the chunksize is set to 314572800 (300M) then the output application bins will be:

This would result in three application packages:

```
foobar-part0-1.0.0.i386.rpm
foobar-part1-1.0.0.i386.rpm
foobar-part2-1.0.0.i386.rpm
```

In general, the chunksize is not a problem unless the application package is almost a gigabyte in size. At that point, some package engines start breaking. The default chunksize is one gigabyte (2 ^30 bytes).

## --solpkgMangle BOOL (SunOS only)

Prevent the ISMTool from changing the name of the application package to conform to Solaris requirements. For more information, see Solaris Differences on page 70.

When creating a Solaris package, ISMTool must use a package name that conforms to the 9-character limit. However, it may be desirable to prevent ISMTool from changing ("mangling") the package name during the --build process. When --solpkgMangle false is specified, ISMTool will use the ISM name when creating the application package. The control package name will continue to be mangled. Note that when --solpkgMangle is false, the ISM name must be 9 characters or less and there cannot be multiple application packages.

## --embedPkgScripts BOOL

Embed the contents of the ISM packaging scripts (installation hooks) in the application package. This option must be used with --skipControlPkg and --skipRunTimePkg.

By default, the application package is built to call out to the ISM packaging scripts installed by the control package. The --embedPkgScripts option overrides this behavior by embedding the contents of the scripts found in the ism/pkg directory inside the application package. These scripts are invoked during the pre and post phases of the application package install and uninstall.

If one or more of the scripts in the <code>ism/pkg</code> directory are not needed, delete the scripts before the <code>--build</code> process. Note that RPM and LPP packaging engines do not have a <code>checkinstall</code> phase so the <code>ism check install</code> file is ignored when building RPMs and LPPs.

# --skipRuntimePkg BOOL

ISM.

Specify whether to build runtime packages during subsequent --build operations.

A runtime package is built by default. If --skipRuntimePkg true is specified, the runtime package will not be built during subsequent operations until --skipRuntimePkg false is specified. ISM utilities such as the parameters interface will fail if the runtime package cannot be located. Do not specify --skipRuntimePkg true unless you are sure the runtime package already exists on the managed server on which you'll install the

## ISMTool Interface Commands

This section describes the ISMTool commands that interact with SA.

## --upload

Upload the ISM contained in the ISMDIR to the software policy specified by --opswpath. If you specify a software policy that does not exist, it will be created automatically during the upload process. To specify which SA core to connect to, use either command-line arguments (such as --softwareRepository) or the environment variables listed in Table 55.

The --upload command prompts for an SA user name and password. Before the upload operation, this user must be granted permission with <code>ismusertool</code>. Also, this user must have write permission on the folder containing the software policy.

IDK Commands 107

### --noconfirm

Suppress confirmation prompts, which require a y or n reply. For example, the ISMTool has the following confirmation prompt:

```
Do you wish to proceed with upload? [y/n]:
```

If --noconfirm is set, the prompts are suppressed and the ISMTool behaves as if the answer is y. The --noconfirm option affects only the current invocation of the ISMTool.

## --opswpath STRING

Specify the path of the software policy that will contain the uploaded ISM. Note that the path always contains forward slashes, even on Windows.

If you specify a software policy that does not exist, it will be created automatically during the upload process. If you specify a folder (a path not terminated by a policy), an error occurs because you cannot upload an ISM into a folder.

The ISMTool supports the construction of cross-platform ISMs. An example of such an ISM is the Network Time Protocol (NTP) daemon, which can be built from source on a variety of platforms. To make uploading of cross-platform ISMs easier, the ISMTool supports variable substitution within the --opswpath STRING. These variables represent the internal settings of the ISM. Table 55 lists the variables recognized by the ISMTool.

Table 55 ISMTool Variables

Variable	Example
\${NAME}	ntp
\${VERSION}	4.1.2
\${APPRELEASE}	3
\${CTLRELEASE}	7
\${PLATFORM}	Redhat Linux 7.2
\${OSTYPE}	Redhat Linux
\${OSVERSION}	7.2

### Unix example:

```
\ is
mtool --opswpath '/System Utilities/${NAME}/${VERSION}/${PLATFORM}' ntp
```

### Possible expansion:

'/System Utilities/ntp/4.1.2/Redhat Linux 7.2'

### Windows example:

 $\$  is mtool --opswpath "/System Utilities/\${NAME}/\${VERSION}/\${PLATFORM}" ntp

### Possible expansion:

"/System Utilities/ntp/4.1.2/Windows 2000"

### --commandCenter HOST[:PORT]

For an upload to a folder, use the Opsware Command Center core component located at HOST [: PORT].

# --dataAccesEngine HOST[:PORT]

For the upload, use the SA Data Access Engine located at HOST[:PORT].

# --commandEngine HOST[:PORT]

For the upload, use the SA Command Engine located at HOST[:PORT].

# --softwareRepository HOST[:PORT]

For the upload, use the SA Software Repository located at HOST[:PORT].

# --description TEXT

Provide descriptive text for the ISM. During the upload, this text is copied to the description field on the software policy.

### --addParam STRING

Add a parameter named STRING to the ISM. Usually, the commands --paramValue, --paramDesc, and --paramType are also specified. For example:

# --paramValue TEXT

Set the default value for the parameter. The --addParam command must also be specified. If the parameter type is 'String' then the value is the string specified by TEXT. If the parameter type is 'Template' then TEXT is interpreted as a PATH to a configuration template file. The data in the template file is loaded as the default value. If the --paramValue and --paramType are not specified, then the default value is the empty string.

# --paramType PARAMTYPE

Set the type of the parameter. The --addParam command must also be specified. The PARAMTYPE must be either 'String' or 'Template'. The default type is 'String'.

# --paramDesc TEXT

Set the descriptive text for the parameter. The --addParam command must also be specified. The default value is an empty string.

### --removeParam STRING

Remove the parameter named STRING.

### --rebootOnInstall BOOL

Tag the application package with the SA package control flag reboot\_on\_install. If -- rebootOnInstall is set to true, then the managed server will be rebooted after the package is installed. If the ISM has multiple application packages, the last package in the list is tagged.

### --rebootOnUninstall BOOL

Tag the application package with the SA package control flag reboot\_on\_uninstall. If -- rebootOnUninstall is set to true, then the managed server will be rebooted after the package is uninstalled. If the ISM has multiple application packages, the first package in the list is tagged.

# --registerAppScripts BOOL (Windows only)

Register the ISM packaging scripts (installation hooks) with the application package.

By default, ISM packaging scripts are encoded in the application MSI to run at preinstallation, post-installation, pre-uninstallation, and post-uninstallation. When -registerAppScripts is specified, the ISM packaging scripts are instead registered as SA package control scripts during the upload. The package control scripts are registered in the Model Repository and are viewable from the HP Server Automation Client.

The --registerAppScripts command is required if the ISM packaging scripts contain actions that conflict with the application MSI installation. For example, a conflict could occur if a post-install script contains a call to msiexec.exe. Since the Microsoft Installer does not allow concurrent installs, a script containing a call to msiexec.exe will not complete successfully. By registering the ISM packaging scripts as SA package control scripts, the scripts are called outside of the MSI installation and uninstallation.

# --endOnPrelScriptFail BOOL (Windows only)

Register to end subsequent installs with the application package.

If --endOnPreIScriptFail and --registerAppScripts are both set to true, then the installation will abort if the ISM pre-install script returns a non-zero exit code.

# --endOnPstlScriptFail BOOL (Windows only)

Register to end subsequent installs with the application package.

If --endOnPstIScriptFail and --registerAppScripts are both set to true, then the installation will abort if the ISM post-install script returns a non-zero exit code.

# --endOnPreUScriptFail BOOL (Windows only)

Register to end subsequent uninstalls with the application package.

If --endOnPreUScriptFail and --registerAppScripts are both set to true, then the uninstall will abort if the ISM pre-uninstall script returns a non-zero exit code.

# --endOnPstUScriptFail BOOL (Windows only)

Register to end uninstalls with the application package.

 $If \verb|--endOnPstUScriptFail| and \verb|--registerAppScripts| are both set to true, then the uninstall will abort if the ISM post-uninstall script returns a non-zero exit code.$ 

# --addPassthruPkg {PathToPkg} --pkgType {PkgType} ISMNAME

Specifies that the package identified by {PathToPkg} should be treated as a passthru package. The supported package type {PkgType} depends on the platform, as shown by Table 56.

{PathToPkg} can be either a full or relative path to the package, but the package must exist at the time the --addPassthruPkg option is specified. {PathToPkg} cannot specify a package in the current ISM's directory structure. For example, the control package, the application package, or a package in the bar directory cannot be specified as a passthru package.

Note that by default, the upload operation does not add the passthru package (specified by -- addPassthruPkg) to the software policy. To add the passthru package, you must specify the -- attachPkg option.

If you upload a Solaris passthru package, the response file is not uploaded. You must manually upload the response file.

The following table lists the allowed values of {PkgType} (package type) for each platform.

Table 56 Supported Package Types for Passthru Option

Platform (OS)	Allowed Value for {Pkgtype}
AIX	lpp rpm zip
HP-UX	depot zip
Linux	rpm zip

Table 56 Supported Package Types for Passthru Option (cont'd)

Platform (OS)	Allowed Value for {Pkgtype}
SunOS	rpm solcluster solpatch solpkg zip
Windows	hotfix msi sp zip

The following example shows how to add a passthru package to an ISM and specify the package for addition to the software policy:

```
% ismtool --addPassthruPkg /tmp/bos.rte.libs.5.1.0.50.U --pkgType lpp ISMNAME
Inspecting specified package: ...
bos.rte.libs.5.1.0.50.U (lpp)
  bos.rte.libs-5.1.0.50 (update fileset)
  IY42527 (apar)
Done.
% ismtool --attachPkg bos.rte.libs-5.1.0.50 --attachValue true ISMNAME
```

# --removePassthruPkg {PassthruPkgFileName} ISMNAME

Specify that an already registered passthru package is no longer a passthru package.

ISMTool will do the following:

- 1 Delete {PassthruPkgFileName} from the ISMs directory structure.
- 2 Record in ism.conf that {PassthruPkgFileName} is no longer a passthru package.
- During the next upload and all subsequent uploads, if the package is added to the --opswpath software policy, it will be removed.

Note that an ISM remembers all packages that have been removed as a passthru package. If a package was added to the software policy via the SA Client or a previous upload operation, the package will be removed from the policy on the next upload operation.

# --attachPkg {PkgName} --attachValue BOOLEAN ISMNAME

Specify whether a package managed by an ISM should be added to the software policy identified by --opswpath.

By default, when control or application packages are built, these types of packages are marked for addition to the software policy. However passthru packages and inner packages are not marked for addition until the --attachPkg option is specified.

{PkgName} is the name of the package as listed by the --showPkgs command. If --attachValue is true, a package is marked for addition to the softare policy. If --attachValue is false, a package will be uploaded into the Software Repository but it will not be added to the software policy. If --attachValue is false and the package already resides

in the software policy, the package is marked for removal from the policy. A package is added or removed during an --upload operation. The following table lists the package types that can be added to a softare policy.

**Table 57 Package Type Properties** 

		Can this package type	
Package type	Can this package type contain scripts?	be added to a software policy?	
AIX LPP	no	no	
AIX Base Fileset	yes	yes	
AIX Update Fileset	yes	yes	
AIX APAR	no	yes	
HP-UX Depot	no	no	
HP-UX Fileset	yes	yes	
HP-UX Patch Fileset	no	no	
HP-UX Product	no	yes	
HP-UX Patch Product	no	yes	
RPM	yes	yes	
Solaris Package	no	no	
Solaris Package Instance	yes	yes	
Solaris Patch	yes	yes	
Solaris Patch Cluster	no	yes	
Windows Hotfix	yes	yes	
Windows MSI	yes	yes	
Windows Service Pack	yes	yes	
Windows ZIP File	yes	yes	

# --orderPkg {PkgName} --orderPos {OrderPos} ISMNAME

Change the install order of attached packages managed by the ISM.

 $\{OrderPos\}\ is\ an\ integer\ that\ specifies\ the\ new\ install\ order\ for\ the\ package\ identified\ by\ \{PkgName\}.\ \{OrderPos\}\ is\ 1\ (not\ 0)\ or\ the\ first\ package\ to\ be\ installed.\ To\ display\ the\ install\ order,\ use\ the\ ismtool\ --showOrder\ command.$ 

The following example shows how to display and change the install order:

% ismtool --showOrder ISMNAME

- [1] test-ism-1.0.0-1.rpm
- [2] test-1.0.0-1.rpm
- [3] bos.rte.libs-5.1.0.50

[4] IY42527

```
% ismtool --orderPkg IY42527 --orderPos 1 ISMNAME
[1] IY42527
[2] test-ism-1.0.0-1.rpm
[3] test-1.0.0-1.rpm
```

[4] bos.rte.libs-5.1.0.50

# --addPathProp {PathProp} --propValue {PropValue} ISMNAME

Specific a value for a property (meta data) of the software policy.

To display the current values, use the --showPathProps command. The following table lists the allowed values and types for the --addPathProp command.

Table 58 Allowed values for {PathProp}

{PathProp} Allowed Value	{PropValue} Type	Example
description	TEXT	'This does something important'
Deprecated:	TEXT	'And so does this'
Deprecated: allowservers	BOOLEAN	false

The following example commands show how to set the description property:

```
% ismtool --addPathProp description --propValue 'This policy does something'
ISMNAME
% ismtool --showPathProps ISMNAME
description: This policy does something
```

# --editPkg {PkgName} --addPkgProp {PkgProp} --propValue {PropValue} ISMNAMF

Specify a value for a given package meta data property.

 $\label{the package to update; it can be any of the package names listed using the --showPkgs command. The following table lists the allowed values for \{PkgProp\}.$ 

Table 59 Allowed values for {PkgProp}

{PkgProp} allowed value	Description	{PropValue} type
deprecated	Deprecated status for package	BOOLEAN
description	Description for package	TEXT
endonpreiscriptfail	Remediation ends on pre- install script failure	BOOLEAN
endonpreuscriptfail	Remediation ends on pre- uninstall script failure	BOOLEAN

Table 59 Allowed values for {PkgProp}

{PkgProp} allowed value	Description	{PropValue} type
endonpstiscriptfail	Remediation ends on post- install script failure	BOOLEAN
endonpstuscriptfail	Remediation ends on post- uninstall script failure	BOOLEAN
installflags	Install flags for package	TEXT
notes	Notes for the package	TEXT
rebootoninstall	Package requires a reboot after install	BOOLEAN
rebootonuninstall	Package requires a reboot after uninstall	BOOLEAN
uninstallflags	Uninstall flags for package	TEXT

The endonXXXscriptfail values are set only if a pre/post install/uninstall script has been defined for a package. These scripts reside in the ISMNAME/pad subdirectory.

Note that not all package types support all the {PkgProp} values listed in the preceding table. The supported {PkgProp} values for each package type can be seen by viewing the package property details in the SA Client. In addition, the following table lists {PkgProp} values supported by specific package types.

Table 60 {PkgProp} Allowed Values by Package Type

{PkgProp} allowed value	Package Type	Description	{PropValue}
upgradeable	RPM	Package is upgradeable	BOOLEAN
productname	Windows MSI	MSI product name	STRING
productversion	Windows MSI	MSI version number	STRING
servicepacklevel	Windows OS Service Pack	Service Pack version number	INTEGER
installdir	Windows ZIP	Installation directory	STRING
postinstallscriptfilename	Windows ZIP	Post install script filename	STRING
postinstallscriptfilenamefail	Windows ZIP	Remediation ends on post install script failure	BOOLEAN
preuninstallscriptfilename	Windows ZIP	Pre uninstall script filename	STRING

Table 60 {PkgProp} Allowed Values by Package Type

{PkgProp} allowed value	Package Type	Description	{PropValue}
preuninstallscriptfilenamefail	Windows ZIP	Remediation ends on pre uninstall script failure	BOOLEAN

The productversion, productname, and servicepacklevel must be set before performing an --upload operation. The productname and productversion cannot be changed after an --upload operation. If you modify the productname or productversion and then perform another --upload operation, the modified values will not be applied.

The following example shows how to specify the description of a package:

```
% ismtool --editPkg bos.rte.libs.5.1.0.50 --addPkgProp description --
propValue 'This is a fileset' ISMNAME
```

# ISMTool Environment Variables

The ISMTool references the shell environment variables described in this section.

### **CRYPTO PATH**

This environment variable indicates the directory that contains the file ismtool/token.srv.

CRYPTO\_PATH and token.srv are required only if you are uploading the ISM from a Windows managed server or a server not managed by SA (that is, a server that has no Server Agent.) To connect to the SA core during the upload of an ISM, the ISMTool needs the client certificate (the token.srv file) that was generated during the installation of HP Server Automation.

Keep in mind that using this certificate with the ISMTool invokes a different security mechanism than the one used by the SA Client. As a result, you might have increased or reduced permissions. You might have access to servers belonging to customers that you usually do not have access to. Also, you might be able to perform operations that you cannot perform with the SA Client. Therefore, in this situation use the ISMTool with caution to avoid unintended consequences caused by a possible change in security permissions.

To obtain the token.srv file and set the CRYPTO\_PATH environment variable, perform the following steps:

1 Log in to the core server as root and locate the following file:

```
/var/opt/opsware/crypto/agent/agent.srv
```

2 Copy agent.srv to the server where you have installed the IDK, to the following file:

```
<some-path>/ismtool/token.srv
```

The <some-path> part of the directory path is your choice, but the subdirectory containing token.srv must be ismtool.

Set the CRYPTO\_PATH environment variable to <some-path>, the directory above ismtool/token.srv.

For example, on a Unix server, suppose that the full path name of token.srv is as follows:

/home/jdoe/dev/crypto/ismtool/token.srv

In csh you would set the environment variable as follows:

setenv CRYPTO\_PATH /home/jdoe/dev/crypto

On Windows, perhaps token.srv resides here:

C:\jdoe\dev\crypto\ismtool\token.srv

You could set the environment variable as follows:

set CRYPTO PATH=C:\jdoe\dev\crypto

### **ISMTOOLBINPATH**

This environment variable is a list of directory names, separated by colons, where the ISMTool searches for system-level tools (such as tar and cpio). The following search strategy is used:

- 1 Search the paths from the environment variable ISMTOOLBINPATH.
- 2 Search the complied-in binaries (if any) in /usr/local/ismtool/lib/tools/bin.
- 3 Search within the user's path.

#### ISMTOOLCC

This environment variable is the <code>HOST[:PORT]</code> of the Opsware Command Center core component used during an ISMTool upload to a folder.

#### **ISMTOOICE**

This environment variable is the <code>HOST[:PORT]</code> of the SA Command Engine used by the ISMTool.

#### ISMTOOLDA

This environment variable is the <code>HOST[:PORT]</code> of the SA Data Access Engine used by the ISMTool.

### **ISMTOOLPASSWORD**

This environment variable is a STRING that specifies the SA password during an ISMTool upload.

#### **ISMTOOLSITEPATH**

This environment variable is a PATH for a "site" directory.

The ISMTool contains certain default scripts and attribute values (for example, the install prefix) which are referenced when a new ISM is created. A developer can override the default scripts and a selected set of attribute values by using a site directory.

#### The defaults.conf File

Within the site directory, a developer can create the defaults.conf file, which contains overrides for attribute values. A line in defaults.conf has the format: <tag>:<value>. A line starting with the # character is a comment. The following example shows the values that can be set in defaults.conf:

#### Unix:

```
prefix: /usr/local
ctlprefix: /var/opt/OPSWism
opswpath: /System Utilities/${NAME}/${VERSION}/${PLATFORM}
version: 1.0.0
ctluser: root
ctlgroup: bin
```

#### Windows:

```
prefix: ???
ctlprefix: ???
opswpath: /System Utilities/${NAME}/${VERSION}/${PLATFORM}
version: 1.0.0
```

### The templates Subdirectory

Developers can override the files in the /usr/local/ismtool/lib/ismtoollib/templates directory by placing their own copies in a templates subdirectory located within the ISMTOOLSITEPATH. For example, developers can override the files that are the default packaging hooks for Windows or Unix.

### The control Subdirectory

Sometimes, developers need to install a common set of tools into an ISM's control directory. The ISMTool supports this requirement by copying all files from a control subdirectory of the ISMTOOLSITEPATH to the ISM's control directory. If a file already exists in the ISM's control directory, it will not be overwritten.

### **ISMTOOLSR**

This environment variable is the  ${\tt HOST[:PORT]}$  of the SA Software Repository used by the ISMTool.

#### **ISMTOOLUSERNAME**

This environment variable is a STRING that specifies the SA user name during an ISMTool upload.

# **ISMUserTool**

The --upload command of the ISMTool prompts for an SA user name. To enable SA users to perform an upload, run the ISMUsertool to assign privileges.

To list the users that have upload privileges:

```
% ismusertool --showUsers
```

To grant a user users upload privileges:

```
% ismusertool --addUser johndoe
```

To revoke upload privileges:

```
% ismusertool --removeUser johndoe
```

ISMUsertool allows you to specify multiple options on a single command line. For more information, specify the --help option:

```
% ismusertool --help
```

By default, the Opsware admin user has upload privileges, which cannot be revoked.

Folders are new in version 6.0 of HP Server Automation. To upload an ISM into a folder, the user must have folder privileges. By default, the admin user does not have folder privileges. In a production environment, admin should not have folder privileges, so you should not use admin for uploads.
